BERLAND, &c.

Part Frees

May it please your Grace,

Do not pretend by this dedication to give a portrait of your Grace's many noble and endearing qualities, because they are confessed by an universal suffrage to be above all panegyric; envy itself being dumb, and lost in admiration, on the mention only of the name of the Duke of NGRTHUMBERLAND: all I mean by it is, to give this public testimony of my obligations to your Grace.

### DEDICATTION.

That your Grace may long live to be a support and ornament to letters; to be a pattern of steady loyalty, legislative wisdom, and to give dignity and lustre to the honours you posses: and that the house of Percy (great and illustrious name!) may, to the latest period of time, have a representative like your Grace, worthy and great in himself, and, after the example of our most gracious Sovereign, King George III, be as much superior to other men in every virtue, as in external grandeur and pre-eminence, is the sincere and ardent wish of

# piles of reiners, or Nobles, of Posters, and the principal. gentry of Lifton De tA had bed or Ad to promoting natural knowledge, and the state of an entry of the provided for the fresh

Britain is indebted for the origin of science to antient Rome, as Rome was to Greece. Their soaring Eagle carried not only victory, but the elegant and useful arts, wherever she had her airy. It was the custom of those sovereigns of the world to polish and instruct, as well as subdue, nations. In Britain, no part had their company more or longer, than Northumberland. Here they had their cities, their castles, and their towns. Here they had their Collegia, their companies, or trades. To the naked and warlike natives they were patrons and protectors, taught them both to cloathe their bodies, and adorn their minds; learned them husbandry, civil polity, architecture, and the polite and useful arts. Thus accomplished and improved the Romans left them.

In the Saxon and Norman ages, piety and learning met with zealous patrons, and bountiful rewards. Churches were built, colleges founded, and both plentifully endowed. Princes and nobles, prelates, ladies, and gentlemen, contended, in a holy emulation, which should contribute most amply and liberally to their support.

Propitious also to the culture of the human mind have been these later ages, both at home and abroad. Under the auspices of Princes, of Nobles, of Prelates, and the principal gentry of Europe, societies have been formed for promoting natural knowledge, and the study of antiquity, to the great emolument and honour of their respective states and kingdoms.

In fuch an enlightened age as this, to fend abroad the Natural History and Antiquities of a County, is an arduous work. How well I have succeeded, must be left to the decision of able and competent judges, possessed of the happy spirit of urbanity and good nature. It is now upwards of twenty years since I first turned my thoughts to the study of Natural History, rather then for amusement, than from any design of casting my observations under an historical form for public view; rocks and dales, woods, heaths, hills, and mountains, the shores of rivulets and the ocean being my company in the hours of leisure and relaxation, after leaving that august and venerable, and truly charming and delightful seat of leatning, the university of Oxford, wherein upwards of seven years of my earliest days were spent.

In my searches after Fossils, I have met with some hitherto supposed by eminent and learned Lithologists not to be of British, but of transmarine origin.

In my Botanic searches, I met with some curious plants on our northern Alps, acknowledged by the indefatigable and accurate Dillenius not to have been seen by him any where in England. Of these, and other curious and useful plants, I have given short descriptions, and have added the synonyms of the most eminent and ingenious authors. Those that would choose to see them under a systematic distribution, I refer them to the elegant systems of Haller (a), and Van Royen (b), and of the celebrated Linnaus.

I have also given short descriptions and synonyms of the most curious Birds observed with us, and of the Insects, &c. with no other embellishments than those of nature and truth.

increase a description of the too the same appears

The works of the British Druids, their cespititious and rocky thrones, temples, and sepultures, attracted my observation; their rude grandeur greatly raising my curiosity.

Northumberland being Roman ground, and receiving my first breath in one of their Castra (c), I was led by a fort of enthusiasm to an enquiry and search after their towns, their cities, and

temples, their baths, their altars, their Tumuli, their military ways, and other remains of their splendour and magnificence; which will admit of a thousand views and reviews, and still give pleasure to such as have a gust for any thing Roman; every year almost presenting new discoveries of the wisdom, contrivance, ingenuity, and elegance of that respectable people; Many of those things which have already come under public notice, I have fet in a new light; and fuch as have not appear in their order under all the advantages they are entitled to. On making the great military road between Newcostle and Carlisle, many foundations of Roman towns and forts have been turned up for the fake of the stones, many valuable sculptures and inscriptions either destroyed or so effaced by the injudicious and undifcerning labourers, that not a Roman feature appears; others have been carried off; and by the death of their first patrons have fallen into lefs curious hands, who have cast them away as Nuga or trifles beneath notice. The incurious hands hath not even spared that majestic monument of Roman opulence and grandeur, The PiEts Wall, one of their greatest 4 works, equally the wonder and admiration of the learned Briton and the inquisitive staanger. That work which with-Rood the shock of ages, was superior to the rage of storms and tempests, the glory, the pride of Northumberland, erected in part at the supplication and importunate tears of Britons, now deplores its ruin by the incurious in Northumberland, by Britons. Dand and reaching Spinish & and was sugar

Many of the Romana exhibited in this work, were never before described; some of them of silver, sculptures, and in relief. Not a few afford excellent precepts to present and suture times. They bring before us, as in perspective, Roman wisdom, Roman piety, Roman loyalty, Roman gratitude, Roman generosity and hospitality, Roman courage and magnanimity, as well under the pressure, as under the exaltations of life.

be some with us by the utmost ferthing. The freedom eli-

The Saxonica and Monastica are as curious and instructive as the Romana. Those ages, enlightened by the bright sun-shine of Christianity, and for the reception of which the Roman manners and politure prepared the way, afford examples of an illustrious piety and a heavenly temper, such as ought to excite our reverence and veneration; the amiable graces of humility, meekness, brotherly kindness, self-resignation, and an indifference to the pleasures, the gaieties, the honours of life, appear often to a degree that is assonishing, only to be copied by those god-like souls who aspire after a happy immortality.

I have spoken of the Religious houses with the greatest impartiality and fairness; described their soundations, their patrons, and their chief revenues, so far as they could be known; given an account of their several prelates, and other learned persons that adorned them.

r. the Regulate of Letters, there is no manuferint

My Mg. Control of the land to Comber to Children in

Bishop Tanner has placed three religious houses amongst us, of whose situation we have no clear account from any good authority. These are Paegnalaech or Womalet, where Bishop Tuda was buried, Warmington, and Nesham (d). We have a maritime place called Nesham, near South Blyth, but there are no evidences of a monastic foundation at it, either from any ruins, from tradition, or from any written memorial. Paegnalaech or Womalet, and Warmington, are no where to be found with us by the utmost scrutiny. The sagacious editor of Bede, Dr. Smith, confesses it to be beyond his penetration and learning to tell where Paegnalaech might be, unless Pinchanheale, or Finchale, near Durham, might be it; a monastery samous in the Saxon times, as attested by the synods held at it, so early as the eighth century (e).

The manuscript of that great antiquary, Bishop Nicholson, intitled, A Description of the antient kingdom of Northumberland, said to be in the library of the Dean and Chapter of Carlisle (f), might probably have given some light herein; but unhappily for the Republic of Letters, there is no manuscript of his Lordship's in that library, except one, relating to his

own diocele, being only a compendious ecclefialtical view of it, in a parochial method; which I looked over by the favour of the present worthyn Librarian, Mr. Wilson, I as Prebendary in that church \* as paid, your of a long of upility is your or

perce of Sir John Chavering, Kt. living in 1-617, with vison All the records taken out of Religious houses on the north side of Trent, at their dissolution, were lodged in St. Mary's Tower at York. Transcripts from them were made by Mr. Dodsworth, which were presented by Thomas Lord Fairfax to the Bodleian library. They are the substance of what the learned transcriber calls his Monasticon Boreale in the manufcripts. In 1644, that repository was blown up by the befiegers of the city. A worthy person, Mr. Thompson, had the courage and resolution, at the peril of his life, to search the rubbish for the records, and was so happy as to retrieve as many, as Mr. Drake calls, A noble magazine of antiquity. Mr. Torr took the pains to put the fair ones into order, marking the places they belonged to alphabetically in a register. They are now in the minster-library at York, but there are no muniments among them relating to the Northumberland-monasteries (g). the street of the Continuous of the Chicagonia

Calleley for a history of Northumberland (b); but I do not find that any thing was done farther than a Genealogy of the family, properly attested by records and inquisitions post mortem, drawn up by Sir William Dugdale, Norroy, king at arms, at the expence of Sir John Clavering, Kt. living in 1617, with whom it ends (i).

The late John Warburton, Efq; Somer set herald, made large collections, respecting this county. They are now in the possession of his Grace the Duke of Northumberland; of which I have had the perusal by his Grace's favour.

I have illustrated the baronial honours, tenures, and feudal property, not from vague and uncertain testimony, but from authorities of the highest pre-eminence in the kingdom; from the Rotuli Annales returned into the Exchequer by the sheriffs, and that grand record, the Testa de Nevill; from Rymer's Fædera, from the acts of the legislature, and from the decisions of the most eminent antiquaries and civilians; from royal charters, family-records and monumental inscriptions.

#### GENERAL INTRODUCTORY DESCRIPTION

O: F

# NORTHUMBERLAND, &c.

With some HISTORICAL ANECDOTES.

Strain the state of the strain of the strain

THE County of Northumberland is of a triangular form, bounded by the German Ocean to the east, the river Tweed to the north, Cumberland and Scotland to the west, the river Tyne and the bishoprick of Durham to the fouth. Its length between the Tyne and Tweed, from Newcastle to Berwick, is fixty-two measured miles and three quarters. Its breadth from Tyne-mouth to Temon-bridge, beyond Glenwelt, is forty-seven, measured. Under the Saxon heptarchy it was part of a large kingdom, founded in the year 547, by Ida, a most accomplished prince; containing all the country between the two feas north of the Humber to the Frith of Edenburgh in Scotland. Hence it has its name. Sometimes it was divided into two, Deira and Bernicia. Deira, i. e. Ferarum Habitaculum, extended from the Oftium of the Humber to the river Tyne; Bernicia, from the Tyne to Edenburgh-Frith (a). By civil diffentions, and the frequent alarms and deprædations of the Danes, it was constrained to submit to the superior power of Egbert, King; en it is a thing of the same and the same of the same

of the West-Saxons, Reg. 28. 828. It was reduced to a province or earldom by Edred, a magnanimous Christian prince, who made Osulph the first earl or governor (b). Those that preceded Osulph, were some of them tributary, and others independent kings, mostly Danish (c). Alfred the Great divided it into shires or counties, viz. Everwickshire, Richmondshire, Coplande, since the bishop-rick of Durham, Westmerelonde, Northumberlonde, Cumberlonde (d). The government of Northumberland by Earls terminated soon after the Norman conquest, and in the person of Robert Mowbray (e). After that æra, it had its Vicecomes, or high sherisf, and was distinguished by baronies, except when it was in the hands of the bishop of Durham (f), and those baronies by six wards, viz.

Tyne-dale, Bambrough,
Coquet-dale, Morpeth,
Glen-dale, Caftle-Ward.

- (f) Scutagium de Northumberland. Quod ideo redditur in j summa, quia comitatus suit in manu episcopi Dunelmensis a quo receptum suit scutagium. Ideo non potuit distingui per baronias.

When the county of Northumberland came into the hands of the bishop of Durham, it could not be distinguished by baronies and districts, as it had been wont before: But the bishop became immediate tenant to the king, of the whole county. And therefore he himself answered escuage for the county in one summ.

Mag. Rot. 6 R. Ric. I. Rot. 10. 2. cited in Madox's Hift, of the Excheq.

The number of boroughs and villas in each ward, and in the liberties of the dutchy of Lancaster, Reeds-dale, Hexham, and Tynemouth-shire, and their antient state, will be best understood by a curious record in the Appendix, No. 1. which exhibits a view of their contributive shares towards the expences of the two county-members, Adomar de Valence, Earl of Pembroke, and Sir Ralph de Eure, of Kirkley, for their attendance in parliament, 5 K. Richard II.

The high sheriff levied by writ the wages of parliament-men. The first writs extant bear date, 28, 29, 32, of K. Edward I; and the first statute, 12 K. Richard II. At the same time that knights of the shire were allowed four shillings a day, burgesses were allowed two shillings, at least, also their travelling-charges to and from parliament. in the reign of K. Edward IV. By a statute, 6 K. Henry VIII, they lost their wages if they returned home without leave from the house (g).

The high sheriff of Northumberland, for the defence of the borders, was entrusted with great power, and extraordinary privileges. He received the issues and profits of his sheriffrick to his own use, with all other debts, sines, and amerciaments, within the county, and all emoluments accruing from alienations, intrusions, wards, marriages, reliefs, &c. In 1549, 3 K. Edward VI. it was enacted, that he should be accountable for his office, as others in the exchequer.

In the parliament summoned to meet, I November, 7 K. Richard II, 1383, an application was made by the nobility and gentry for a part of the public levies to be assigned them for guarding

<sup>(</sup>g) Statutes at Large, An. 6 Hen. VIII.

the borders against the incursions of the Scots, who were answered, that they had a sufficient recompence by the tenure of their lands, given them for that particular service (b).

It was enacted in the parliament, called in October, 9 K. Richard II, 1385, that all possessor of lands on the marches beyond the river Tyne, whether lords or others, should reside upon them, except such as the king should think sit to dispense with (i).

Northumberland hath given the title of Duke and Earl to many noble personages. It gave the title of Duke to John Dudley (k), and the title of Earl and Duke to Charles Fitzroy (l), and of Earl for a small space to John Nevill Lord Montacute. It hath given the title of Earl to no less than thirteen of the noble family of Percy. The present Earl was created Duke of Northumberland, 6 K. George III, October 3d, 1766.

Northumberland is in the diocese of Durham, whose prelates are princes palatine, having temporal as well as spiritual jurisdiction, being stiled in antient pleadings, Palatii Comites, Earls of the Palace, as to their temporals; and are said to hold episcopal state, as to spirituals (p).

The

The liberties of the county palatine of Durham were afcertained by parliament, 11 K. Henry VI; on a complaint being made in a petition to the house of lords by bishop Langler, of certain compositioners sitting and making enquiry at Horton-Pool in his county palatine; after many learned pleadings used by the attorney general, Sir William Earl, Knt. to prove, that his lordship ought to have no county palatine, or liberties royal (q) and be at the provention of the palatine of of the p

In parliament-time, the bishops of Durham and Carlisse were excused their attendance, on sending procuratores sufficientes, sufficient proxics, as by their place they were to have a vigilant eye to the defence of the borders; and in the writ for the parliament to meet at Westminster under K. Edward II, they were expressly inhibited to be present otherwise than by proxies, worthy, says the record, of being representatives in that great council of the nation (r).

The bishop of Durham had a suffragan, or an episcopal coadjutor, 28 K. Henry VIII, 1536, whose see was at Berwick upon Tweed (s),

This bishoprick is rated in the king's books at 1821 l. 1s. 5 d. and before the reformation was rated in the Pope's books at 2025 l. and paid for the pall 2000 l. (t). Every clergyman on admission into a benefice, paid one year's profits to the Pope, under

to melong sulcomented

The present number of parochial churches and chapels in them, the extra-parochial and peculiars, their patronage, and the appropriations, will appear with precision and accuracy under the following view. But I must first premise, that the ford high chancellor nominates to all preferments in the gift of the crown, valued at 201. per annum, or under, in the king's books; and the record of parliament, which recognizes his fordship's right, 4 K. Edward III, particularly mentions the end for which the grant was given by the crown, viz. to enable him to provide for the clerks in chancery, and other courts, who in those days were persons in holy orders; and accordingly the direction even in the record is, that he should give such benefices to the king's

<sup>(</sup>u) Statutes at Large, An. 27 R. Hen. VIII.

clerks in the chancery, exchequer, and both benches, and not to others; the chancellors themselves being generally ecclesiastical persons. I shall take no notice of their annual value, being variable and uncertain, rarely understood by any but their possessors.

For most of the Vicarages we are indebted to the statute made by the parliament at Westminster, summoned 12 Nov. 14 K. Richard II, 1390, empowering the bishop of every diocese on the taking a licence out of chancery for the appropriation of any church, to make some provision by Money, arising from the profits of it,

enter the second of the second

for

for the perpetual maintenance of a minister or vicar (v); religious communities enjoying before that time the whole profits to themselves of an appropriation given them, one of their own body doing the parish-duty Bedn

By an act of parliament made, 9 K. Henry V, 1421, every third benefice in the presentation of the bishops or monasteries was to be conferred on some scholar of Oxford or Cambridge, for the encouragement of learning (w).

What might antiently be the number of inhabitants in Northumberland, cannot be determined with precision. No light can be had from the famous furvey of K. William I, the most decifive record in the kingdom; heither this country, or the counties of Westinorland, or Cumberland, being included in it; nor had we the use of parochial registers till the reign of K. Edward VI\*; many of which have fince perifhed. But it is supposed that, at present, they may be about one hundred-thousand, of which feventeen-thousand appeared on the constables lists for to bear arms, exclusive of Newcastle.

The foil of Northumberland is various. On the borders of rivers. and on the sea-coast, it is remarkably fertile, abounding with rich meadows, pattures, and delightful corn-fields. To the northwest, and south-west, it is very mountainous; and to the west full of heaths, fens, and lakes; but fome of those heaths, abounding with mines of rich ore and coal, and others being or the presentation of Machineller, formmoned to Nov. 14 K. Richard

very improveable, and capable of culture, and the mountains feeding vast multitudes of sheep, render Northumberland a very opulent county. Our wool brings home to us the wealth of the remotest kingdoms, and our lead and coal give us the treasures of our neighbours both at home and abroad. There is hardly a gentleman, but who has all the necessaries and conveniences of life on his own estate. The barrenest hills, and the lakes and rivers, contribute to his health and delight, by giving him exercise, and furnishing his table with plenty both of sish and sowl. It is, indeed, very naked of timber in most places, except on the banks of rivers, and some pleasant and fertile spots, and by gentlemen's seats, with great judgment reared and preserved, for pleasure, shade, and shelter.

Some of those seats are good old castles, built upon rising hills and eminences, not so much for shew as defence, to have a better prospect of an approaching enemy, such as before the Union were the Scots, and a fort of thieves, called, Moss-Troopers, whose custom it was to pillage the country, and to retire into the western and northern wastes, and other inaccessible places in Tyne-dale, Reeds-dale, Glendale, and Gilsland, on the borders (x); from whom it was hard for any one to get his goods again, unless he applied to a master-thief with a fee in his hand, which they called, Saufey-Money (y). After the union, these and other irregularities were wisely suppressed.

As before that glorious period, the two bordering, and now fifter-nations, difplayed great heroifm in the defence of their

<sup>(</sup>x) Bernard Gilpin's Lise by Dr. Geo. Carleton, Bishop of Chickesler, inter collectanca Batesiana, 4to. 1628. His Lise by William Gilpin, 8vo. 1753.

<sup>(</sup>y) Grey's Chorographia, in er collectan. Oxfordiana, 4to. vol. iii. Vol. I.

respective liberties, so at present there subsists as eminent a friendship and harmony between them; conferring on each other all forts of good offices, the one frequently making alliances by marriage with the other. And certainly, it is a very fingular bleffing and advantage to us of this kingdom, and especially to us of this county, to be united to so very antient, and in many respects, to such a brave people. For amongst them we find a numerous, antient, and polite Nobility. Their GENTRY are men of great humanity, fagacity, and honour; well instructed in letters; commonly polished and improved by their travels; and their conversation agreeable to all their neighbours. As for their Commons, they are a very laborious, hardy, and industrious people; fitted for the hazard of the seas, and capable to struggle with the greatest difficulties by land, They have a natural prowefs and gallantry for war; they are brisk in the field, and healthy in the camp; they are men of sagacity in council; they are prudent and confiderate in conduct; they are brave and gay when they enter upon action, and inferior to no nation in the world when they are to execute any bold and daring enterprize. To have fuch a people to fupply our navies with experienced mariners; to have fuch a nation to fill our troops, and increase our armies; to be united to such a kingdom, fo gallant and capable to fight our battles; this is adding a visible ftrength and support to our glorious crown and monarch; this is giving undeniable fecurity to our civil state and government. By this we escape all those evils, and fad calamities, which must attend an island governed by two independent fovereigns. If we look back into our antient histories, we there read a dreadful account of the former cruel and unnatural wars; the barbarous treatment one nation shewed the other, the burnings and defolations that often happened; and the frequent inroads

roads that were made upon this and other bordering counties: if we but view the many murders, outrages, and continual robberies almost daily committed; and observe how in former ages the kingdom of France was almost always strictly leagued with the Scotch Kings: if we but confider, how conveniently that kingdom lies for the incendiaries of Europe to form all their bloody defigns against us, how continually we were exposed, what hazards we run, when a Scotch independent Sovereign had a distinct power, and could at pleasure open those sluices, which should let in a deluge of miseries upon us: upon all these accounts, we have a great deal of reason to bless the divine preventing grace in removing those evils, and placing them at the greatest possible distance from us. Great is the cause we have to bless the day, when we began to wear the name and character of GREAT BRITONS. We of this County have shared largely in the bleffings of that day, which I cannot help celebrating; and may it long be celebrated in the British annals, and the latest records of time! We have had opportunities of looking more inquifitively into our rich and wealthy mines, and have drawn forth in greater quantities those useful and hidden treasures, wherewith the divine providence hath, in a distinguishing manner, enriched this mountainous part of our British isle. We have had opportunities of augmenting our trade, of improving our barren lands, of making public and private roads, and of doing many other laudable and good things, of which I shall take notice in the course of this work.

#### CHAPTER I.

### OF THE HEAVENS AND THE AIR.

XTRAORDINARY appearances in the heavens naturally excite our attention. In February, 1737, between the hours of three and four in the afternoon, we had an Annular Eclipse of the Sun, which was acknowledged by the learned to be the most entertaining spectacle they had ever seen in the heavens.

This phenomenon was feen at Long Framlington, at Alnwick, and Berwick. It continued between four and five minutes at this last place. Its duration at Alnwick was not measured. At Long Framlington, the Annulus was observed to be very small on the upper part by Mr. Long of that place, and its continuance 40 or 41 half seconds, measured by a Pendulum 9, 81 inches long. This was its southern boundary. The eclipse was not annular at Morpeth and Newcastle. The body of the moon appeared almost entirely on that of the sun at Morpeth, and to the naked eye the disk of the sun seemed to be almost round. There wanted about 40 degrees of the limb of the sun to appear, in order to form an Annulus at Newcastle, according to the observation of Isaac Thompson, Esq.

Vol. I. B

The northern boundary of the Annulus was beyond Inverness in Scotland, but how far could not be precisely determined. Very accurate observations were made of it by many curious persons in that kingdom \*; and particularly by the famous mathematician, Colin Mac Laurin, of Edinburgh, who gave an account of it to the Royal Society †. They all had in view, as well as the philosophical observers with us, the ascertaining the motions of the moon on Sir Isaac Newton's theory upon which a good deal of the doctrine of the longitude depends. Sir Isaac's calculation, with respect to the beginning of the eclipse, was observed to be pretty exact, but with regard to its central appearance not so accurate.

The air was cold both in *Scotland* and *Northumberland*, at the time the observations were made, and there was a little thin fnow and ice towards evening, about four o'clock.

A Lunar Annulus, or a ring or circle about the moon, of a vast circumference, was seen by myself and family at Simonburn, 31 Oct. 1762, at 8 o'clock at night; bright and luminous on its first appearance, then changing to a beautiful azure; and, at length, after half an hour's display of its splendor, sunk gradually into deeper shades, till it entirely vanished. The Area between it and the moon was magnificently spaceous, a deep blue, the horizon clear, the night frosty. The night following, November 1st. there was an eclipse of the moon, which began at 17 minutes past 7 o'clock, and ended at 5 minutes past 10. A great death followed among men and horses by a yellow fever.

<sup>\*</sup> The Lords Abardour, and Hopton; the Lord chief Baron Clerk; Mr. Bayne, professor of the municipal law; Mr. Short, Mr. Fullerton, of Fullerton, near Air; Sir Thomas Wallace, at his feat near Lockryan, in Galloway.

<sup>+</sup> Ph. Tr. Nº 447.

At the same place, 19th March, 1763, half an hour past 8 o'clock at night, we were entertained with the sight of a Lunar Iris; the extremities of the arch east and south, the moon to the southwest, affording a good light, but few stars appearing. At 9 o'clock it vanished, when innumerable stars arose in view, and enlightened the horizon. We had boisterous winds, frost and snow, for several days after it; the night of the 21st dreadfully tempestuous, and that of the 24th and the two days following remarkably severe by a fall of snow, and a keen frost.

There is no better proof of the falubrity of the air with us, than the long life of the inhabitants; fome living to eighty, fome ninety, and fome an hundred years. The laft vicar but one of Hartburn, the Revd. Mr. Laton Eden, brother to Sir John Eden, Bart. was 51 years vicar of that parish, and lived to the age of 90. He was interred within the rails of the chancel of his own church, under a flat stone, Dec. 6th, 1735. A clergyman, now living, has been incumbent of a parish forty-eight years, after the possession of another above eight, and had a curacy and a college-fellowship before that, is healthy and agil, and capable of going thro' all the duties of his function, or the cares and fatigues of life, with the youngest man \*. Ann Tellford, a poor woman of Haughton, near Humshaugh, could fee to thread a needle at the age of 103, and died at 105, in December, 1759. In the village of Wark upon North Tyne, I have fometimes asked the age of a man and his wife, and the reply made by each of them has been, "above fourfcore, "Sir!" A case not unfrequent among the common people in that village and neighbourhood; which is attributed to the frigidity and purity of the air, whereby their folids are braced, and perspi-

<sup>\*</sup> See an extraordinary account of the age of a clergyman, near Alnavick, in Fuller's Worthies, in a letter to that author from Thomas Atkin, Esq; son to a chief magistrate of the city of London, p. 308-9.

ration not promoted to excess by labour and exercise. Add to this, the hardy way of living of the poorer fort; their bread being made of barley and peas, and their chief subsistence milk and cheese, curds and whey, and potatoes, seldom eating butcher's meat, and but rarely having any malt-liquor in their families; their dwellings often consisting of two rooms with earthern floors, and unsealed; the one occupied by themselves, and the other, perhaps, by their cattle; the air in blowing weather entering in at the chinks and crevices, and making the faces of young children, and even the aged, look as rofy as apples in autumn; the children going in the coldest day in winter without shoes and slockings, often not from necessity, but choice: all which strengthens their bodies, preserves their constitutions sound, and gives them a floridness of countenance, to be seen only in such as are used to so good an air.

Here is, generally, fuch a ferenity of air and fine weather in autumn, that it is a kind of fecond fummer; many flowers blowing vigorous and strong, with as much beauty as in the spring.

For two or three years past, indeed, the air has been of unequal temperature throughout the seasons; the spring sharp and severe; the summer for a day or two excessive hot, succeeded on a sudden by chilling colds, and showers of hail; the autumn as variable as the summer months. A few days followed by others tempestuous and rainy, scarce admitting the harvest to be got in, especially near the dreary moors and wastes; the winter frosty for a night or two, and then unexpectedly followed by a thaw, and often by heavy rains. This inconstancy of the weather, sudden heats and sudden colds, has very bad effects on animal bodies, checks the motion and elasticity of the sluids, casts the fanguine into severs, the weak and the feeble valetudinary into the hypo',

many of the able industrious poor into agues and sluxes, though not mortal, yet bringing them under the fear, and almost under the fight of, a grave. The poor cattle are also sensible of it, cows especially; whose milk becomes coagulated, thick, and viscid; a watery, stringy humour falling from their nostrils; their cheeks swelled, the pain forcing tears from their eyes in heavy drops. But be it remembered, that this is the state of the air only for a few years past, and not peculiar to this county.

Thunder-Storms are not very frequent. A little before Midsummer, in 1756, we had a very remarkable one; the lightning and explosions dreadful. It entered and demolished all the windows of the New Inn at Chollerford-Bridge, upon the banks of North-Tyne, except those in the kitchen, overturned a chest of drawers standing against the wall between two beds in a chamber on the first floor, did not touch the fore-part next the windows, but shattered the back-parts, not injuring the beds. The family in the kitchen were under great consternation. Mrs. Lightfoot, the land-lord's wife, happened to have a child in her arms, with which under her surprize and terror, she fell to the ground, but providentially neither she or the child received the least harm.

We had a very uncommon Thunder-Shower, with aftonishing flashes of lightning, on Friday afternoon, 18th June, 1760, at Simonburn; the air still, serene, and warm, the sky clear, except a black cloud. It continued three quarters of an hour. In that small space, the rivulet of Simonburn rose about sourteen feet perpendicular by Nunwick-bridge. Diminutive and scanty streamlets assumed in an instant almost the pomp of rivers. Huge rocks rolled in the waves, in company with large roots and trunks of trees, which were scattered on the adjoining meadows, and in a pleasant garden of Sir Lancelot Allgood's at Nunwick, where the soil, slowers, and various plants, were swept away, and a great deal of

other damage done to roads, fields, and hedges, not repaired without a confiderable expence.

On Sunday evening, 12th July, 1761, there was another Thunder-Shower at Newcastle and Rothbury, such as had not been within any man's memory at the latter place, where the Coquet rose to an amazing height, entered the nursery and garden at Rothbury-hall, on an eminence, destroyed several thousand fir-plants, and left many cart loads of stones and pebbles in their room.

By the favour of our hills and mountains, the receptacles of winds, we are preferved from the more frequent visits of this dreadful artillery of the skies, lightning and thunder, which in a mineral country, like this, would otherwise be very common; the winds, which are nothing else but air agitated and put in motion by our all-powerful and wise Creator, drive before them and disperse the nitrous vapours and exhalations, and make a pure and falutary horizon.

The great autumnal florm in 1756, which was fo general and fatal in other counties, was in this very boisterous, but did not do any other injury, besides making terrible slaughter, if I may so speak, of large and stately forest-trees in our woods and plantations.

Storms of Hail and Snow are frequent with us. In 1760, Dec. 24, about 6 o'clock in the evening, we had at Simonburn a heavy flower of hailstones of a peculiar form, of the fize of the tip of a man's little finger, with a flat basis, angular and pointed.

Shrove-Sunday, 21st Feb. 1762, was very snowy and tempestuous; the snow driven into prodigious heaps in several places by a boisterous wind, sharp and piercing, filling our imaginations with fear for the safety of every living creature exposed to its unrelenting rigour.

Monday night, 8th March, 1762, and the next day, were much like that Sunday, both for fnow and wind; the vallies and hollows rifing to hills of fnow among our mountains; and every where elfe we were prefented with fnow-profpects till Thursday-night following, when the scene was changed by rain and a high wind, which blowed very loud till morning, but the rain continued till Saturday, and a lowering, hazy sky compleated the thaw. These two storms were general through the kingdom, and were fatal both by sea and land; ships and their cargoes, and the brave sailors, superior to all other dangers, perished in the sea, and many unfortunate persons were suddenly cut off.

About fourteen years ago, as the fun was croffing the line, the weather was fo flormy and tempestuous, that the sea slowed and ebbed twice at one tide, at *Blyth*; the waves, in their approach to the rocks, magnificently terrible.

Blights, of a pernicious nature, feldom infest this country. The worst that I have observed happened 31st May, 1759, and 1st June, 1760; both in the night. In the morning, the woods, and hedge-rows, and nursery-plants, particularly ashes, appeared in mourning, their young shoots and leaves scorched and shrivelled, and made coal-black by a piercing vapour and keen frosty air, the ground being covered with a hoar-frost in the morning of the first of June. Trees and shrubs of a hardy nature, whose shoots and leaves were better guarded against its virulence, escaped unhurt.

Polyfillabical Echoes are generally thought worthy of remark. We have two of these, very curious and uncommon. One is under the bank on the north-side of the river Coquet, opposite to a farm-yard by Mr. Clutterbuck's summer-house, at Warkworth. It will return seven notes from a German slute in a still evening. In

a rough unpleasant one, 30th Sept. 1761, it repeated fix very distinctly. The arch or pillar of the bridge seems to give it.

The other is at the fame village, on an eminence by a fmall cottage on the fame fide of the river, opposite to the castle. It repeats the words,—

Arma Virumque cano (VIRG.)

very articulately, and fix notes from the fame instrument. The locus polysonicus seems to be the castle, from which it comes in such soft and pleasing harmony, as if the castle was enchanted, and it was the voice of a Syren.

#### CHAP. II.

#### OF THE WATERS.

which, according to the Greek philosophy of Thales, he calls the Parent of all Things. He finely imagines a person to enter into the bowels of the earth to satisfy his curiosity, where he sees Nature in her subterraneous palace, on crystal thrones, and surveys fossil-woods, and groves of metal, and lakes and rivers taking their course to their mother-ocean\*. But at the same time he observes, that such a research—est tangere Limina Divum; which may serve as an admonition not to be too inquisitive into natural causes, to explore them with modesty—cum fas est—when it may be done without presumption, and then imploring the divine blessing. He makes his Aristaus not to enter upon his subterraneous adventure without divine permission and authority. And, at length, he represents him in an act of religious adoration.

Discordant are the opinions of modern adventurers in this enquiry concerning the source of rivers and fountains; one, with the great *Mantuan*, his countryman, a *Florentine*, of noted fagacity and penetration, ascribes it to the sea by secret subterraneous

<sup>&</sup>quot;Oceanum patrem rerum." †

<sup>\*</sup> Virg. Geo. 1. 4. v. 365, &c.

<sup>+</sup> Ibid. v. 381-2.

currents\*; another to fubterraneous refervoirs†; fome to rain and fnow ‡; others to the Vapours of the fea, rain, and fnow. This last fystem is most generally received, on the evidence of the great Dr. Halley, Mr. Ray, and Dr. Plott ‡.

The confideration of the difficulties attending both this and the other fystems, undoubtedly led the learned *Stukeley* to speak of this subject with the piety and modesty of the divine *Mantuan*. He speaks of it, when he has the healing fountain of *Buxton* before him, as a secret still impenetrable by any human genius.

"I observe, says he, that the whole country hereabouts is a rock of good lime-stone, which is the minera of the water's heat and virtue; but how that comes to be calcined; by what refined chymistry of nature sulphur and steel is mixed with it; by what means it acquires and conserves with so much constancy this equable and mighty focus, together with the reason of sountains in general: I profess, in my sentiments, is one of the great arcana in philosophy hitherto inscrutable ||."

I do not think that any one county in this island can boast of finer rivers and brooks than this. The Tyne, the Blyth, the Wanf-

beck, the Coquet, the Aln, and the Tweed, enter like fovereigns into the ocean with their tributaries, and all, but the Coquet, receive ships into their bosom with great pomp.

Our Lakes or Loughs of principal note are,

Crag-Lake, fo called from its fituation under a range of steep rocks of whin-stone on the north side of the Roman wall, opposite to their station of Little Chesters, and to the 31st mile-stone on the military road, is half a mile long, and about 400 yards over. It is shallow at the east, and of a great depth at the west, end; the bottom of fand and gravel; no reeds or rushes in it, except in the deepest part; a pleasant alpine farm on a slope by its eastern margin, and another at the west end, on a slope likewise, both belonging to William Lowes, of Ridley-Hall, Efq. In the range of rocks are many irregular perpendicular columns of a furprizing height and magnitude, one standing by itself, like a Druid pillar, towards the west end. Some seem as if they were ready to fall, and others lie in amazing numbers on the bank below, to the very brink of the lake, beaten down by tempests. Among these are many curious plants. In the clefts, and on the broken fides of the taller columns, are the quicken-tree, the elder-tree, the burnet-rose, and the beautiful rose-bay willow-herb. In the hollows, the dove-coloured falcon with black pointed wings

annually rears up its young, making the rocks and water echo on the approach of danger with a harsh sonorous note, somewhat resembling that of a goose. Between the brink of the rocks, at the top, and the Roman wall, is a broad grass-terrace, from which, in looking down the steep, and upon the water, our minds are on a sudden silled with a reverential awe, and we are naturally led to think of our great Creator, especially in a still summer's evening, when the clouds are imaged by the water, representing castles, cities, groves, and forests, and these spired rocks, with their vegetable ornaments, in most wonderful grandeur and magnificence.

Greenley-Lake, so called from its lying at the foot of a fine green slope, is a mile and a half long, and about a quarter of a mile over in the broadest part, towards the middle. The bottom is of white fand and pebbles; the fouth-west end adorned with the double white, and the yellow, water-lily; an abundance of reeds and rushes by them cross the lake. That beautiful falcon, the bald buzzard, called by our shepherds, the bastard-eagle, breeds annually on the mosses near it. It is partly in view from the terrace above Crag-Lake. A boat was formerly kept in it for the pleasures of angling by its late owner, Sir Edward Blacket, of Hexham, Baronet.

Little Cow Lake, so called from its smallness and the cows drinking in it, and cooling their limbs among the weeds on its sides in sultry weather, is on the south side of Greenley-Lake, to which it is a fort of an appendage; there being a communication between them by a small current at the east end; a ridge of moor parting them, on which is a cottage, affording a view of both. It is a mile north-west from the Roman station of Honse-steeds.

Bromley-Lake is a mile north-east from the same station; and at the west end of the ridge of rocks at Sherving sheels, by the Roman wall. It is a noble piece of water. It is a mile long, and half a mile broad; not a weed or a rush in it, except a few at the west end; the bottom of white sand and pebbles. On a slope at the south-east end is a ridge of rocks, in which is a natural stonegrotto, the roof of one entire stone, rising obliquely to the horizon, eighteen feet long, terminating in a point from a broad base; giving a full view of the lake, formed like a bason, with sloping banks. It is on the estate of William Lowes, of Ridley-Hall, Esq; and in the manor of Sir Edward Blacket, of West Matsen, Bart. as are the three lakes before described.

Halypike-Lake is two miles east from Bromley, and a mile north from Shewing-sheels. It is small, the bottom of sand and pebbles; the west end of a great depth, abounding with rushes, and the two water-lilies, the double white and yellow; the two galeated or hooded purple loose-strifes in a bog beyond them. It is on the estate and in the manor of Sir Lancelot Allgood, of Nunwick, Knt.

Grunden-Lake, fo called from its fituation on a low ground, den, or valley, (our northern people calling ground, Grund) is a mile fouth-east from the Roman station of House-steeds, and in view from it. It is long and narrow, stretching east and west about a mile; the bottom of white sand; of a great depth at the west, and shallow at the east, end.

Shilden-Lake, corruptly for Sheel-den Lake, i. e. the lake near the fheels or house by the den or valley of South Tyne, is near Corbridge, in fight from the thirteen mile-stone on the military road by the Roman wall, from which it is about a mile. It is about half

half the fize of Bromley-lake; the bottom muddy; very pleafant in fummer.

Sweethope-Lake is about a quarter of a mile east from great Waneyhouse-Crag, near Tone. It is small and narrow; the bottom stony; a large marsh at the west end, which is over-slowed in winter. At the east end is a corn-mill which it supplies with water. It had a neat boat for the diversion of angling, which is now lying as a wreck on its banks; the boat-house also in ruins at the north-east end.

Belfay-lake is of about the fize and shape of Grunden-lake, in a field by the road on the east fide of the village.

Prestwick-Carr is near a hamlet of the same name by Pont-Eland. In summer it covers about ten acres of ground, but much more in winter. In a very dry summer it had so little water, that a great many roots of trees were visible, and in some the marks of the ax were easy to be distinguished.

Harebottle-Lake is about a mile west from the castle of Harebottle; formerly an alpine garrison, as its name imports, from the Saxon Hare, the station of the army. It is a small lake.

Newham-Lake, so called from its situation near a small village of that name, i. e. the lake by the New Hamlet, is near Bambrough-castle. It is a pretty large lake.

Kim-mere, i. e. the Mere or lake, by the Kemb or fort, of which there are the remains of one or two near it (Mere being a corruption of the Latin Mare, and Kemb a word used by the Scotch and English borderers to signify a strong-hold, designed for defence, and for drubbing and kembing an enemy, as they phrase it) is a

short mile fouth from Eglingham. It is a small, but pretty area of water; an abundance of that fragrant shrub, the Sweet Gaul or Dutch Myrtle on its banks. These lakes are all well stored with pike and perch, and some of them with dace and roach; the largest perch in Crag-lake.

Our fanative and confecrated springs are numerous. The spring of highest medical fame at present, and most frequented, is one between Learmoth and Cornhill. It is commonly called,

Cornhill-Well. It is of a ferruginous taste, not unpleasant. The sides and bottom are coated with yellow ochre, the martial earth, the Residuum or rust of iron. It is a powerful absorbent and dissolvent, as appears by the tinctures it gives with the following drugs. With powder of galls, an astringent, it yields a deep purple; with syrup of violets, a grass-green; with oil of tartar per Deliquium, or with spirit of sal ammoniac, volatile alcalies, a milk-white. Spirit of nitre, an acid saline liquor, makes no change in it. Experience has proved it excellent for curing inveterate, stubborn scurvies, and the gravel. A cold bath is erected near it, at the expence of Henry Collingwood, of Cornhill, Esq; neat, and cased with lead, filled and emptied by turning a cock. It is in a fine healthy country, by the rich and fertile haugh or vale of Wark, and the beautiful salmon-streams of the

Tweed, the fairest Caledonian Flood \*.

At Tweed-mouth, is a facred fpring nearly allied to it in virtue, and of late much reforted to for the fame complaints. It is called our Lady's well, being dedicated to St. Mary.

<sup>\*</sup> Brown's Piscat. Eclog. p. 98.

A mile and a half east from Rothbury, by the turnpike-road to Alnwick, is a spring called, Dibden-well. It has a strong current; a yellow martial earth so copious by its adit, as to be taken up by handfulls. By it is a stone-bath. It is much used for feculent scorbutic eruptions, both by bathing, and drinking it with Epsom falt. It is a very cold spring in the hottest day in summer, of an irony taste.

There is another near the West-Hall, at Belford, dedicated to St. Stephen; used for the gravel, with Castile-Soap, and has been found an efficacious remedy.

At Fleetham, near Bambrough, is a spring much commended as a pectoral, and for obstructions. It was thought by a late eminent physician at Berwick, Dr. Forster, to have the slavour of the Pyrmont-water, and to have its virtues in an inferior degree.

In the Duke of *Northumberland's* park, at *Alnwick*, called *Huln*-park, is a fpring found by trial to be of the fame nature with the *Tunbridge*-waters.

On the brow of the hill at Allen-dale town, is a chalibeate spring; the Terra Martialis, or ocherous Residuum, copious upon the herbage by it.

At Newbrough, near Hexham, is a spring of the same kind; sacred, and dedicated to St. Mary.

There is another at Jefmont, near Newcafile; facred also, and of the same dedication, walled round with stone; a saffron-yellow ochre appearing on the sides, and a blue vitrioline sediment at the bottom. It is a plentiful spring. It is made to fall into a stone-bath, a little below it. In the monastic times it was much

fre-

frequented by pilgrims. It is faid then to have had as many steps down to it, as there are articles in the creed.

Below the garden of William Swinburn, of Long Witton, Esq; on the margin of the Wansbeck, to the north-east, is a winding path through a wood of fine young oaks, leading to three facred medical fountains, called Thurston-Wells. They issue out of the bottom of a high ridge of rocks of coarse rag-stone. The western one is the largest and neatest; so full of yellow-ochre, both at the bottom, and by the adit, that it may be taken up with one's hand; under it a vitrioline sediment of a bluish grey. It has been found of great service in the cure of sore eyes, of obstructions, of the scurvy, and agues.

Under the brow of a hill at East Unthank, on the banks of South Tyne, is a medical spring of similar virtues; the martial earth, both brown and yellow, copious on the stones and herbage by it. Experience, the best test of the nature of any spring, has proved it to be an excellent remedy for pectoral complaints; giving appetite, and promoting perspiration; also good for joint-tumours, and for agues; curing an ague, even when the samous Analeptic, the Cortex Peruviana, has failed. A well like this, and those at Thurston, a specific for agues, is described by Dr. Scipio de Moulins at Canterbury \*.

We have a fpring at Acton, near Blanchland, little inferior in medical virtues to the Unthank-spring, especially as a pectoral, in removing obstructions, and restoring appetite.

Among the lead-mines, at Allen-Heads, is a medical spring, used with success for scorbutic fæculencies and the gravel. It

\* Ph. Tr. No. 312.

is of an atramentous taste, owing to an alcaline cretaceous earth.

At the village of Halywell, near Seaton-Delaval, in a field called the Park, is a fpring of fimilar qualities, and would undoubtedly be as efficaceous in the fame complaints, but it is not put to any medical use that I hear of. It is of a stong atramentous taste, and turns to a deep purple with galls. It is dedicated to St. Mary, and is called the Haly-Well; from which the village takes its name.

In the stone-pavement of the rivulet, on the north-side, next the village, is a vitrioline spring, very perceivable in a dry summer, rising in perpendicular bubbles; a yellow ochre, or martial earth, plentiful on the pavement by it. It is of an irony taste.

There is another of the fame kind a little higher up the rivulet, by a flate-quarry. They are both known to the neighbourhood, but not used. They give a purple with galls.

Besides these chalibeate vitrioline springs, we have others, which, from their remarkable charge of sulphur and sætid taste, are called Sulphur-Springs.

By the rivulet of Wark, in Tynedale, near Rose's Bower, is a spring so impregnated with sulphur, that the scent of it is perceiveable above two hundred yards in hot droughty weather. A blue sediment is then at the bottom, which being rubbed on one's singers makes them of the same colour. The sides are tinged with an ochreous yellow. The stones and herbage, washed by its current, are of a silvery hue. With an infusion of galls it turns to a deep purple, and with syrup of violets to a faint green. It is unaffected with oil of tartar per deliquium, and with sal ammoniac.

It is much used for agues, the gravel, and other obstructions, for which it is found by experience to be effectual. It is under the brow of a hill, the fides and cover at top of unwrought freestone; of a triangular figure; shaded above with nut-bushes, and other brushwood, through which is a cart-road; the current to the north-east, into the rivulet of Wark, within a stone's cast, mufical with its murmurs on the stone-pavement, and through broken rocks; the opposite banks, covered with wood, musical likewife in a fummer's evening with the cooing of turtles: the Villa of Rose's Bower hard by, and in fight from it, on the brink of lofty precipices; a fmall streamlet having a fall from one of them into a large hollow, whose steep and rocky sides being shaded with various kinds of trees, the ash, birch, tall elms, and the quicken-tree, the white-thorn, and the verdent ivy, make it look like a bower, of difficult access; increasing in beauty by the fight of the rivulet of Wark falling from another rock just above, between a hanging bank of brushwood, and broken crags and cliffs, imaged by the water; the receptacle or bason of water under it of a considerable depth.

A quarter of a mile above the romantic ruin of Staward le Peel, on the edge of the river Allen, is a fulphur-spring, dedicated to St. Mary, called the Haly-Well. It is in the Sinus of a sloping freestone-rock, wherein are lodged large pellets of sulphur; the aperture and sides tinged by it with a silvery colour. It is of a nauseous fætid taste and smell. Being so near the Allen, the sloods often encroach upon it, and force it to change its situation in the rock, breaking out again in some other aperture. The situation is extremely pleasant; a bank of tall oaks and other forest-trees on both sides of the river; an upright stone-pillar by it, sit to rest a book on; the river within

a few yards forming a cascade, called Cyprus-Linn; under it a large and deep bason.

On the western slope of a mountain, near Knaresdale-Hall, is a sulphur-spring, called Snape-Well. It is of a sætid taste, and so cold in the hottest day of summer, that to the touch it seems like ice. It is much used for chronical disorders, and the scurvy. It is a plentiful spring. By it is a stone-bath.

We have fome fprings which, from their remarkable charge of Allum, are called Allum-Springs.

Under the brow of the hill, about a mile north from Simonburn, is an Allum-spring, called Conchilton-Well. With powder of galls it turns black, as the blackest ink, and a grass-green with syrup of violets. It undergoes no change with oil of tartar per deliquium, or with spirit of sal ammoniac. It tastes strong of allum, is rough like it in the mouth, attended with a bitterness. It is used for agues and sore eyes, for which it is much commended. It is overslow'd by a small streamlet after great rains; and seems originally to have been the outburst of a coal-mine,—Fons per accidens. It was first observed and used by a poor man, from whom it has its name.

At Swallowship, near Hexham, is an Allum-spring, formerly of great note, but now neglected. To feeble and languid constitutions, oppressed with scorbutic fæculencies and obstructions, it has been known to give powerful and speedy relief. The widow of the late Reverend Mr. Robley, of Simonburn, was reduced to great weakness by scorbutic tumours in her legs, for which she drank the sulphur-waters at Wardrew, in Cumberland, without effect; but drinking those of this spring, she assured me, she was perfectly

feetly cured: and also affirmed, that a poor man, deprived of the use of his legs by the scurvy, and sorced to walk with crutches, was cured at the same time, after having tried other means without success.

These are the chief sanative springs we have. It is an extraordinary providence, that in this cold northern region, where scorbutic disorders are so frequent, that we have so many such springs for our relief.

It is the caution of an eminent physician to forbear the use of spirit of vitriol, Spiritus Nitri dulcis, and such like acids, as a diurctic, in drinking mineral waters, unless in some hot inflammatory cases, to alter and diminish their force. To recover their strength when thus weakened, he recommends the insusion of an alcali-salt, such as volatile salt of hartshorn, or of sal ammoniac, or fixed salt of tartar, or of wormwood, which will restore their virtue and medical power. The use of Lacticinia, or any kind of milk, he thinks so far from being injurious in the course of drinking them, that he prescribed milk to be given to puny stomachs in an evening with good effect \*.

The learned naturalist, Francesco Redi, of Arezzo, in Italy, disapproves of low spirited persons drinking freely of them, for fear of injury from the mineral Faces, which make sad work in the sluids of hypocondriacs  $\dagger$ .

There are some facred fountains with us of no reputed medical virtue, yet are held in a considerable degree of esteem and veneration, for their being antiently appointed to religious uses. There is one at

<sup>\*</sup> Frederick Slare, M. D. Ph. Tr. No. 337.

<sup>†</sup> Opere de Francesco Redi, 4to. Florent. 1724.

Wall-Town, near the Roman station of Caervorran, where Paulinus is said to have baptized King Egbert, and some thousands of his subjects. It has been walled round with freestone; some of the stones, neatly hewn, still lying by it. There is another at

Halystone, a place of early note on the first introduction of christianity amongst us; Paulinus being said to have baptized 3000 souls at it. This well is a beautiful bason of water, rising at the east end in bubbles perpendicular to the horizon, with fine green sand. The bottom is variegated with it and white sand. It is walled round with freestone, hewn-work, two or three courses still standing, shaded with trees and shrubs. It belonged to a priory of Nuns.

In a hanging wood, on the fouth fide of the brook at Simonburn, is a well dedicated to

St. Mungo, or St. Kentigern, Bishop of Glascow, whose life was written by Joseline, a monk of Fourness, in Lancashire, which is in the British Museum among the Books of Sir John Cotton.

Among the fea-rocks, on the north fide of the church at Newbiggen, is a facred fresh-water spring, called, St. Mary's well, over which the tide flows.

The fprings dedicated to the honour of St. Mary, are numerous. There is one at Huln-abbey, near Alnwick, and another at Tillmouth.

The practice of confecrating springs is very antient. Sometimes they were confecrated for a living memorial of extraordinary mercies received from heaven, in the patriarchal ages; sometimes for a testimony of important Fadera, compacts or covenants, entered into among men; and sometimes for their heal-

ing virtue. Hagar, the mother of Ishmael, addressing herself to God by a fountain in her distress, and being visited by an angel, and receiving consolation, she called it, Beer-la-hai-roi, that is, the well of him that liveth and seeth me, to perpetuate the memory of his providential care over her\*. Abraham entering into a league or covenant with Abimeleck, mutually strengthened and consirmed with an oath by a fountain, he called it Beer-sheba, i. e. the well of the oath, and by this well be planted a grove, and called there on the name of the Lord, the everlasting God †.

The Roman festival Juturnalia was instituted in honour of a sanative fountain, called, Juturna, a juvando, near the river Numicus ‡.

Many fprings and rivers were confectated by the Romans for their religious rites, for their lustrations at funerals and facrifices, and before they entered their Sacraria, or temples. Of this kind was their Fons Blandusia, and their Flumen Clitumni ||. And of this kind, probably, is their well here at their station of Carraw-brough, called,

The Roman well. It is between two floping fields, on the west side of the station, just under it, to the south of their famous wall, about 400 or 500 yards from the 25th mile-stone on the military road; square, and faced with freestone, of hewn-work;

<sup>4</sup> Hor. Od. 13. l. 13.

<sup>|</sup> Virg. Geo. 2. v. 146.

and has either had a dome over it, or been walled round; the stones now lying about it, nearly covered with water from the conduit's being stopt, and demolished by the carelessness or ignorance of a plowman, as I am informed; it is full up to the brim, and overslowing, in the hottest summer; and by that man's indiscretion, he that would fatisfy his curiosity to see it, must risque the wetting his feet, especially in winter, or in a rainy season.

Our Northumberland-Saxons, in their Pagan unconverted state, had their confecrated lakes and rivers. Such was Haly-pike lake; and such was the river Wan's-beck, a contraction of Woden's-beck, from Woden, the Saxon Deity.

Springs remarkable for their lapidescent quality, converting plants into stone, and assuming their image and figure, are not very plentiful with us. At *Bedlington*, is one called, *Spinner*'s well.

On the north fide of the brook at Simonburn, below the school-house, is a water which has this property, attended with this singular circumstance, that its terrene salts make a change in some plants, and not in others, though growing in a group together, Mosses and Liverworts becoming stony, and Primroses and Geraniums holding up their heads, and retaining their native form and hue. The reason assigned for this phenomenon by a learned naturalist is this: the former being destitute of congenial salt, readily admit into their pores adventitious ones; the other being already furnished with it, will admit of no heterogeneous accession\*.

In Honeyclugh, near Chesterwood, below a small cateract, there are two rocks in a manner formed of incrustations by the continual

<sup>\*</sup> Dr. Plot's Staffordshire.

dripping of a petrifying water; the incrustations of various colours, with small hollows and arches of fretwork and petrified moss. They are two of the most beautiful groups of petrifications that I have observed any where with us.

Cateracts, or Water-falls, prefent themselves in many places among our mountains and hills, in great magnificence and beauty. The rivulet of Chetlup, near the high mountain Reed-fquire, has a fall of seventy feet. It is called Chetlup-Spout.

The Coquet, a mile below Rothbury, by a corn-mill and a flatequarry, had formerly a great fall, but has been lowered to favour the afcent of the falmon up the stream. A few yards lower down, that fine river is confined between two rocks, and may be stept over with great ease, entering them with musical sympathy from little slopes and precipices. Its contracted current is here called

The *Thrum*. It is in length about fixty yards; in breadth one yard, where narrowest, and there four yards deep, when the river is low, and the summer dry and fine. The mountain-tor-rents or floods have pierced the rocks, of ordinary freestone, into numerous holes, some of them resembling little furnaces or caldrons.

Near the mountain of Little-Cheviot, three miles north-west from Ingram, is a cateract, called,

Linhope-Linn; also Roughting-Linn, from its noise in its fall after great rains; the word roughting being also used by the borderers, on hearing the lowing and bellowing of cattle. It is nearly perpendicular, forty-seven feet and a half, from a rock of brown whin, spotted with green; the bason seven feet over, and in depth Vol. I.

fifteen feet, measured by a line and plummet, in September, 1761; the weather fine, and the water low. It is a trout-stream, pretty sizeable trouts being taken in it above the fall. It was the custom of the late Colonel Moor, of Halystone, to put them into such places, obscure alpine rivulets and lakes.

A mile to the north of Bellingham, is a cateract, called,

Hareshaw-Linn. The fall is about thirty feet. The precipices below rife to an amazing and frightful height, in a semilunar form, of the arenaceous laminated kind; the Sorbus aucuparia, the oak, and other trees, fastening their roots in them; the ivy, capillary, and crustaceous plants, variegating their sides. By the brook, and in the middle of it, are rocks fallen from them of a vast magnitude, upon whose tops are Vaccinia nigra, Fragraria, and the Burnet rose, and other plants. In the eastern precipice, by the water-fall, is a semicircular stone-grotto, with a stone-seat in it, the canopy over it large, but from the nature of the rock too dangerous to be frequented for pleasure, the loose parting stones being objects of horror.

At Tecket, near Simonburn, is a water-fall between two dreadful precipices, which feem every moment as if they would tumble down. Above it, the water runs on a natural stone-pavement for a considerable space; and at a small distance from it, on a rising ground, pleasantly facing the south sun, is a natural stone-grotto, with a stone-seat in it; and at one corner a cavity, resembling a stone-cupboard. The roof, or canopy, is one solid rock of a vast magnitude, of the coarse rag or millstone-grit, resting with its north end in the ground. So many uncommon objects presenting themselves to our view, render this a very romantic spot, fill our minds alternately with wonder and amazement,

and are monuments of the tremendous power of that Being who formed them, pointing out to us obedience, and an humble dependence upon him.

Below the water-fall, opposite to *Tecket*, the brook enters a fubterraneous cavity under a great rock. It keeps its fecret course for a mile and a half, and then rises in perpendicular bubbles, in a field near *Nunrwick* Mill, after supplying which with its strong and clear stream, it falls into *North Tyne*. After heavy rains, and great snows, the greatest part of it is carried off in a strong and rapid current past *Tecket*, between two hanging banks of wood, where, by various falls from broken rocks, it forms a most romantic and beautiful scene.

CHAP.

#### CHAP. III.

#### OF EARTHS.

THETHER Earth or Water contribute most to the growth of vegetables, has been a question much debated by phyfiologists. Antient fages have fancied water to be the mother to earth itself. Those great moderns, Mr. Boyle and the Lord Bacon, have taken not a little pains to elucidate her maternal right; but the learned Dr. Woodward has, by feveral curious experiments, evinced, That water has no claim to a priority in natural productions; that they are rather coadjutors; that in all water there is a terrestrial matter fit for vegetation, in leffer or greater proportions \*. Some plants are more vigorous, and their flowers more vivid and glowing, and fome trees of a bolder stem, and of a more gloffy and luxuriant leaf, which have but a little earth and moisture; others require a greater store of both; and we fee a variety of different forts, both annual and perennial, the root, foliage, and the flowers, receiving their growth and beauty from the pabulum they find in the fame fpot of ground, and from the ambient air and dews; but by the most vigilant attention we cannot diffinguish the terrene falts and juices closely approaching their feveral roots. If we take away the earth from about them, and put in fresh, we see them thrive with great luxuriancy and beauty, though of a different genus, and containing different falts in their composition. It is therefore with great probability imagined, that the contextures of their

<sup>\*</sup> Thoughts and Experiments on Vegetation, by Dr. Woodward, Ph. Tr. No. 253.

lovely forms, from the first germinating of the seed, however minute and invisible to our eyes, are the natural limbecks, wherein the terrene salts, water, air, rain, and dew, are digested in several varieties.

Many families of plants, both herbaceous and arborefcent, are vigorous and healthy in the chinks and crevices, and fummits of rocks and precipices, with little visible earth to fustain them; and many of the marine tribes on testaceous bodies, both fed with the nutriment they find in such situations. Their seeds, roots, stems and leaves, are the proper strainers to generate their sluids, and to concrete them into their several falts, to which the external compressing air in the several changes of summer, autumn and winter, are auxiliar till they come to maturity. The native sluid and sap in trees hardens into timber, and its annual revolutions are prettily displayed in circles. Its original principles are earth, water, and air, fermented into peculiar salts by more curious strainers, and by more subtil menstruums than art hath hitherto discovered.

Husbandry and planting have of late years rose to a considerable degree of perfection in some parts with us. Our vale-earths are so naturally rich, that by a moderate labour they answer our most fanguine expectations. I cannot but lament the steril aspect of many thousand acres in the west, and north-west, and of some tracts also in the midland and maritime parts, all capable, by divivision and inclosure, of the ornaments of tillage or planting. The bringing them thus under cultivation, instead of being oppressive to the poor, as alleged by the inconsiderate, would raise them from indigence and poverty, to competent and easy circumstances. The very planting of large portions of heaths and hills, and the making roads of pleasure or carriage to them, would

would find employment for a multitude of poor, whose families would otherwife be flarving by the precarious dependence on the milch of dwarf-cows, horses, and sheep, lean and hungerflarved, ranging in fwarms on the wastes. Let the rocky hills of Brissley near Alnwick, of Rotheley, of Camboe, and the grounds about Wallington, be testimonies of the felicity and smiles of the poor employed in planting them, and making roads; comfortably fed and cloathed! Let the divided commons of Hexhamshire, of Shilden, of Simonburn, and feveral wastes by the military road, be remembered, and paralleled with the common and township of Wark upon North Tyne \*, for instance, and with the large one above Bellingham, and its neighbouring townships. In the former, agriculture exalts her head; the plowmen, jolly, rofy, and robust; some of them in as happy a state as the famed Coritius, described by the excellent Mantuan in his fystem of husbandry †. In the latter are all the marks of beggary and want, meagre faces, empty cupboards, whole families of both fexes, and of all ages, taking their weekly, monthly, and quarterly circuits, and levying contributions by alms on their happier neighbours; multitudes of them wandering, not from inclination, but called abroad by hunger and pinching necessity.

This is the real flate of our improved and unimproved commons. Who that loves his country, and is moved at the prospect of so much wretchedness; who that prefers plenty to poverty, pleasure to distress, a society to a desert, would not give his voice for a general inclosure and distinction of this vague property, and rescue it from so much wretchedness? We should presently see a fort of new creation, new towns, a new people, busy and industrious, well cloathed, well fed, enough for the culture of rural

<sup>\*</sup> Since divided.

and domestic arts, and enough for national service; an accession of wealth and felicity to the subject, and of power, opulence, and greatness to the sovereign. The accomplishing this glorious work will, I hope, be the care of those, whose province and interest it is to consider the national good, to disfuse and distribute public and private blessings, to promote population, and an increase to his Majesty of industrious, loyal, and faithful subjects.

We cannot fland excused, if we deny to our country those improvements, which it demands from its natural advantages. It is open to the sea. The shores, at certain seasons, are covered with the sea-wreck; many of our creeks with sea-shells. Many of our fields and commons abound with limestone; and not a few with excellent cretaceous earths or marles.

The Sea-Wreck, for a light foil, defigned for barley, or oats, is a rich manure for two or three crops, giving an extraordinary increase.

Sea-Shells, for all kinds of foil, but a fandy one, are a good and permanent manure. The antient practice was to burn them \*, but they are found by experience to produce better crops of corn without it. The corn is fair and well-bodied. The herbage is thick, short, sweet and fine, mixed with daisies and flowers, recreating both the tenant and the passenger with their fragrant odours.

The Calx viva, or limestone, affords a valuable manure. Strong lands manured with it, bring, for two or three seasons, fair and beautiful crops of corn, especially wheat, barley, and peas; and then converted to grass, produce a short, sweet, and lovely

<sup>\*</sup> Ray's Schect Remains, Itin. iii. p. 245.

fort, mixed with daifies, and yellow, crimfon, and white perennial clovers, eat up to the very roots by the sheep and cattle. Our limestone earths, a natural loam, may be distinguished from all others in the spring by their herbage, enamelled and tissued with a variety of odoriferous and fanative plants, the primrose, cowslip, and oxlip, daisies, and violets, clovers, and all the self-heals, both carmine, purple, and white, giving a delicate slavour to the mutton fed with it, a fine grain and texture, and colour, beautifully marbled with fat and lean, affording rich gravies, and by nice and curious palates preferred to venison. Our dairies by such herbage have a preference to all others; the butter as yellow as gold, and of a fragrant sweetness; the milk light, and free from gross juices, and of a pleasant taste.

It is furprifing, that turnep-husbandry should be so much in fashion, which spoils the dairy, and the shambles, sends such gross-flavoured milk, cream, and butter, beef and mutton, to our tables. It is well enough for a Succedaneum in the cold wintermonths, or in unfavourable summers for grass, but to give it so much of our care and attention, to the neglect of other cultures, the cherishing of natural herbage, can be nothing but the effect of avarice or sloth.

Cretaceous earths or Marles are of admirable use in husbandry, in the culture of all kinds of lands, designed either for grass or corn. We have them of various colours, and of various degrees of strength and goodness, in several places.

A reddish-brown marle is in a considerable quantity at *Ilderton*, near *Rodham*. It is of a firm and close texture, unctuous in handling, slightly colouring the singers, and slowly diffusible in water, It melts in the mouth, and has no disagreeable taste; pure, and free

free from grittiness. Dry, and scraped, it shews a glossy polite surface. It effervesces with Aqua fortis. In the fire it acquires a brighter colour. It is a good manure for light hungry lands.

An ashen blue marle, with a slight admixture of a pale yellow, is at Chillingham, but not plentifully. It is heavy, of a compact texture, and unctuous to the touch. It makes an easy solution in water, and is of a sweet astringent taste, free from grittiness. Depurated, and worked into a paste, it is ductile, and has a glossy beautiful surface on being cut through with a knife. Applied to the busts of coins and sygnets, it takes them off easily, and shews their beauties and defects with extraordinary exactness. It effervesces with Aqua fortis. In the fire it acquires a considerable hardness, and a duller colour, with a slight cast of a reddish-brown. It is a good manure for light, poor grounds. It is used in taking grease out of boards and woollens.

In a great marle-pit at *Etall*, by the road to *Ford*, on the left hand, is a ftratum of dufky reddifh-brown marle. It is heavy, and fhattery, on being cut through with a fpade; unctuous to the touch, but does not colour the fingers; melts flowly in the mouth, and feems between the teeth like hard foap, pure, and free from grittiness; flowly diffusible in water. Depurated, and worked into a paste, it cuts through with a glossy surface. It does not effervesce with *Aqua fortis*. It crackles in the fire, and acquires a great hardness and a dull red.

In the fame pit is a stratum of friable greenish-yellow marle. It makes a quick solution in water, and sends up a great number of bubbles. Dry, it powders the singers. It effervesces with Aqua fortis. In the fire it acquires an orange-colour, and a more Vol. I.

shattery texture. Great quantities of it, and of the former, have been digged for a manure.

A friable ash-coloured marle, with a slight admixture of yellow, is on the common adjoining to a farm, called, the Stone-Honse, by the road-side, near Shitlington-Hall, in Tynedale. It is in a stratum of a considerable thickness. It is heavy, and mode-rately friable; falls in shattery pieces on being cut with a spade; colours the hands, and is freely disfusible in water. Depurated, it works pleasantly into a passe, not viscid or tenaceous. Smoothed with a knife, and cast into a slow fire, it acquires a pale whitish-red colour, and a fine skin, equalling some of the Roman, unglazed, siguline vessels that I have seen fragments of at their stations of Condercum and Corcester. It is well worth the trial for the better fort of pottery, as it is to be had in sufficient quantities. It does not effervesce with Aqua fortis. It would be a good manure, but is put to no use at present that I know of.

On the edge of the brook above *Tecket*, in the grounds belonging to the small hamlet of *Overton*, is a friable whitish-yellow marle. It is harsh to the touch, colours the hands, disfuses freely in water, and sends up many bubbles. It does not effervesce with *Aqua fortis*. In the fire it acquires a great hardness, and a duller colour. It is used to give hearth-stones and chimney-pieces a stone-colour. To the inclosed commons now under culture, it might seem to be no contemptible manure; but, I suppose, the great plenty of lime is the occasion of its neglect.

Just under the hill before the farm-house at West-wood, near Hexbam, is a friable white marle. It was only lately discovered in making a cut for a fence. It is in a kind of bog; the stratum three yards thick; great numbers of shells of the small fresh

water turbo, or whilk, immersed in it. It is unctuous, and cuts through with a shining surface; colours the hands; dissurfaces in water freely, and is very gritty. Dry, it is powdery and rough. It effervesces with aqua fortis. In the fire it acquires a considerable hardness, and a duller colour. It is little used as a manure, for the same reason, probably, that the former is not; lime being had in great plenty in the neighbourhood.

A friable grey marle, with the same kind of shells, is in a large boggy area by a farm, called Sunnylaws, near Wark, in Glendale; the stratum of a considerable thickness. It is heavy, unctuous, and stains the hands; disfuses freely in water, with a hissing noise, and bursts into a fine powder, with hardly any grittiness. Dry, it is powdery, and crumbles between the singers. It makes a violent effervescence with aqua fortis. In the fire it crackles a little, and acquires a more brittle texture, and a bluish-grey colour. It is used as a manure, and is accounted excellent. It has not been long discovered.

There is a variety of it at Grindon, near Norham, with the fame kind of shells.

I am informed by my worthy friend, Henry Collingwood, of Cornbill, Efq; that he has also a variety of it with these shells on his estate at that place.

A brownish-red stony marle is in considerable quantities at *Ilderton*. It is heavy, and with some difficulty diffusible in water. It breaks slowly in the mouth with some gritty particles, of a harsh and nauseous taste. Depurated, and worked into a paste, it cuts through with a glossy surface. It effervesces with aqua fortis. In the fire it crackles and bursts, and acquires a great hardness, and a dull red colour.

These are the natural advantages and encouragements for husbandry with us. The present state of it, improved soils, and method of culture, shall be our next consideration.

The vale between Aldston-Moor and Nerveastle upon Tyne, is a very rich natural soil, well wooded, watered by the Tyne, and a variety of musical streamlets, turns greatly to the profit of the husbandman, grows remarkably sine wheat, and such luxuriant, sweet, and fattening grass, that an ox, fed at Bywell, and killed at Corbridge, 1756, weighed, when cut in quarters, 112 stone. The manure chiefly used in this vale is limestone, burnt in large kilns, generally built of stone.

About Newcastle, a cold and hungry clay prevails, yet every field appears by culture like a garden, plentifully manured with dungs, some native, and vast quantities extraneous, brought at an easy expence from London, by way of ballast in the coalships.

The fea-coast is chiefly a strong clay, manured about Whitley with lime; to be had no where else between the Tyne and Coquet, east of the post-road.

Many of the farmers between *Hartley-Pans* and the *Coquet* procure limestone in small sloops from *Sunderland* in the bishoprick of *Durham*; with which, and the sea-wreck laid in heaps and rotted, they have good crops of all forts of grain.

From the *Coquet* to the *Tweed*, the ground is annually loaden with valuable grain, peas, beans, barley and wheat, and with fuch feeding grafs, that fome of the largest and fattest oxen are fold there, which are commonly fold to the butchers of *North-Shields*, for the ships in the coal-trade, and to the contractors of

the navy. The chief manure is limestone, had in great plenty in feveral quarries.

The banks of the river Tweed in Norhamshire, and about Wark and Carham, are a fine fertile loam; the manures chiefly lime and marles.

Glen-dale is mostly a light, arenaceous brown earth, improved with dungs and lime; the crops rye, barley, peas, and wheat.

The vales of Whitingham, Wallington, and North Tyne, are a good foil, argillaceous in general, but in fome places a brown loam and gravel, especially in the low shadowy meadows, by running streams.

After this representation of the state of husbandry, of the improved soils, and method of culture amongst us, I shall now take notice of our earths which are of use in other arts.

The white foap-earth, or Steatites, the Paratonium of Authors (a), is found in small veins on Calleley-hill. It is of a beautiful white, of a close texture, and glossy surface, when cut, feeling soft and unctuous to the singers, but not colouring them; breaks freely; melts in the mouth into a substance like cream, and in water is disfusible, making a slight ebullition; ductile and tough under moisture. It does not effervesce with aqua fortis. In the fire it crackles and bursts, acquires a moderate hardness and a duller colour. It was one of the native colours used by the antients in

<sup>(</sup>a) Steatites quæ Parætonium antiquorum. Da Costa, Nat. Hist. Foss. p. 35. No. 13. Woodw. Cat. Foss. c. a. 13.

Arigilla albissima ponderosa tenax. Quæ Parætonium Authorum. Hill. Hist. Foss. p. 17. No. 1.

painting in Fresco, for which they held it in great esteem. It is supposed not to have been in any plenty with them, as they are said to have adulterated it with the Cimolia. They had it from Cirene, from the island of Crete, and from Paratonium in Ægypt; from which two last places it obtained the name of Cretan Earth, and Paratonium. It is only used at Calleley in whitening hearthstones and chimney-pieces.

The purple and white foap-earth, the Steatites vera (b), is found in veins on the fame hill, by the road-fide. It is white, with streaks of different degrees of purple. It is of a fine, close, and equal texture, and glossy surface; fost and unctuous in handling, not colouring the singers; not melting in the mouth, nor dissussible in water. Cut through in the vein, it breaks into irregular pieces. It does not effervesce with Aqua fortis. In the fire it acquires a considerable hardness. From its resemblance to hard soap, it has its name of soap-earth; and the name of Steatites, from siap, such, from its likeness to the fat of animals. The antients called it Cimolia, from the island Cimolus, now called Argentire, where it is found in great abundance.

There is a variety of it at the same place of a beautiful peachblossom colour.

These stony saponaceous earths being somewhat of a taley constitution, are classed by Linneus, and others, among taley soffils; but the justly celebrated Da Costa, and Dr. Hill, have referred them to the class of clays, as having on trial all the properties of an indurated clay.

It is faid this beautiful species of clays enters into the compofition of the porcelain made at Worcester; of the art of making which, and the true substances used for that purpose by the Chinese, we have an excellent and curious account by Monsieur de Reaumer (c).

On the shores of our alpine brooks and rivers we often find a species of this fossil so remarkably lapidescent, and so elegantly variegated, as to carry the appearance of a marble. It is called by some of our common people Clay-marble. It is the Morochtus of authors (d); of which I have met with several varieties.

If. Of a fky-colour, elegantly clouded with a light and deep red; with an arborefcent delineation like the trunk of a tree, and a figure fomewhat like a bird at the top of it, in the attitude of taking wing. From the fhore of the brook at Gofton.

2dly. Of a grey and red colour, in lighter and deeper shades, with bluish-black spots and *Dentritæ*, and the figure of an animal, resembling a pig, in the attitude of swimming.

<sup>(</sup>c) Hist. et Mem. de l'Acad. Roy. des Sciences pour 1727.

<sup>(</sup>d) Morochtus. In Germania, et Anglia, reperitur. Charlet. Foss. p. 30. n. 14. Steatites tertia. Da Costa. Hist. Foss. p. 40. n. 16.

Morettum album rectius Porcellana nativa. Bruckm. Epist. Cent. ii. Ep. 100. p. 1244. n. 10. et seq.

3dly. Of a bluish-black, variegated with red and white.

4thly. Of an ashen colour, with two different shades of purple, and arborescent strike or dendritie of a dark purple.

5thly. Of a fky colour and carmine, with deep purple ftriæ. These four from the shore of the brook below Simonburn-castle. The last is not unfrequent on the shore of North Tyne, by the Strother-house, below Chipchace-mill.

Another species of this fossil, the Melitites of the Antients (e) is sometimes found on the same shores. The ground-colour is a fair pale yellow. I met with the following varieties of it.

If. Of a light straw-colour, with beautiful purple veins.

2dly. Of a straw-colour, variegated with red, and elegantly punctated with black. Both these from the shore of the brook at Goston.

3dly. Yellow, with a mixture of red, diffused in clouds, and zones or circles of red, edged with yellow, resembling little slowers, of the size of a sixpence; not superficial, but pervading the whole substance. From the same shore.

Beautiful varieties of it are also not unfrequent on the shore of North Tyne below Chipchace-mill, and on the shore of the brook below Simonburn-castle, especially after sloods.

Rubbed on a stone with water, all the kinds yield a milky, sweet solution, like cream; from which property the Melitites has

<sup>(</sup>e) Steatites indurata Melitites dicta. Da Costa. Hist. Foss. p. 41. n. 17.

Argilla indurata albo-slavescens lævis, quæ Melitites Antiquorum. Hill. Hist. Foss. p. 24. n. 14.

its name, from  $\mu$ ehl, Honey. Drawn on a board, they make a white line. They do not effervesce with Aqua fortis. Under proper management, they are capable of a fine polish. Drinking-cups, and other things, were formerly made of them abroad, in the Margraviate of Bayruth, polished after a curious manner, but the art is said to be now near lost. They are used in making the finest Porcelain, for which they are excellently well qualified; the tale in them being proof against fire, and preventing a perfect vitrification.

Mineral Agaric, or Lac Lune, a fine loose friable earth or chalk, the Seleneufia of the Antients (b), is found plentifully in the perpendicular and horizontal fiffures of a freeftone-quarry on the west fide of Hall-Barns, near Simonburn. It lies in the form of a farinaceous powder, on thin, sparry plates. It is of a bright white colour. It is extremely foft in handling, colours the fingers, melts freely in the mouth without the least grittiness. In water it makes an ebullition, and gives it a milky colour. It makes a violent effervescence with Aqua fortis. It was valued among the antients as an aftringent, and used in hamorrhages. They used it also as a cosmetic, to cleanse the skin, and deface wrinkles. Scilly affords the finest, from which they had it. The Germans are faid to have used it with success externally, in drying all kinds of ulcers; and internally, in all diseases proceeding from the acids; in hæmorrhages, and pestilential or malignant fevers. It is commended as an excellent abforbent.

Vol. I. Cat. A. a. 62. Cat. 1. a. 49, et Cat. l. a. 28, et 29;

At a place called Black Sheel-Bog, near a coal-work, two miles fouth from Haltwefel, is an argillaceous pale yellow earth, mixed with white, and spangled with flat talcy particles. It is unctuous in handling, slightly colours the fingers, and is easily broken. In the mouth it is gritty, and of a nauseous taste, which goes off with a kind of sweetness. In a glass of water it bursts into a powder, and stains it with a bright yellow. Depurated, and worked into a paste, it is of the same colour, and of great tenacity. It does not effervesce with Aqua fortis. In the fire it acquires a stony hardness, and a light red colour, variegated with white, looking like a marble. The sloors of the Roman ovens at their station of Caervorran seem to have been made with it. It is used by skinners and glovers in dressing and colouring their leather; for which use it is carried in great quantities so far as Westmorland.

There is a vein of the fame kind by the brick clay-pit near the High-Sheels on Hexham-common; many loads of which are carried to Newcastle for the use of the same trades. It is a species of Fuller's earth.

At West Thurston, near Felton, is an argillaceous earth of an ash-colour. It is of a dense compact texture, unctuous to the touch, melts slowly on the tongue, with a little grittines; breaks and moulders in water with difficulty. Depurated and worked into a paste, it assumes a milk-white colour, and cuts through with a glossy surface, and on being smoothed with a knife, has a sine skin when dry. It does not effervesce with Aqua fortis. In the sire it acquires a dull white colour. It is used at the glass-houses in Newcastle for making surnaces, or vessels, that will bear an intense sire; for which use it is not inferior to any in Britain, in

the opinion of Dr. Woodward (g), and only rivalled by the Sturbridge-clay. It has been worked for many years, and still holds its reputation. The mine is about twenty fathom deep; the clayvein three feet thick, under a variety of strata, one of coal; it is lett, worked, and sold by the ton; yielding 3 l. per ton.

On Acome-Fell, near Hexham, is a brown argillaceous earth, with a yellowish cast. It is harsh to the touch, tough, and ductile. Thrown into water, it makes an ebullition, with a slight noise, and after some time moulders to a powder, a little gritty. It effervesces with Aqua fortis. In the fire it acquires a dull red-dish-brown. It was lately used in making a fine black earthern ware, by a person well skilled in the figuline art from Stafford-shire.

The Rubrica molliuscula, the softer reddle (b), is not unfrequent. It is heavy and of a compact texture, unctuous, and staining the singers; harsh to the taste, and somewhat gritty. It is diffusible in water, and gives it a deep claret colour. Depurated, and worked into a paste, it cuts through with a glossy surface. It does not effervesce with Aqua fortis. In the fire it acquires no change of colour. It is the soft clay iron-ore of Dr. Woodward (l). The miners call it the Mother of the Mine. Others call it Smit, from their marking their sheep with it. It is used by pain-

ters, and makes a red little inferior to the *Indian* red earth. This here described was taken out of the cavity of a large free-stone.

An indurated deep red ochre, the Rubrica durinscula, the harder reddle, or red chalk of authors (k), is dug among the sea-rocks at Bednel. It is heavy, of a sirm, compact, and even texture; of a smooth surface, and somewhat unctuous; stains the hands extremely much; melts freely in the mouth, of an astringent taste, pure, and free from grittiness; makes no ebullition in water, and with difficulty diffuses or moulders to pieces in it. It does not effervesce with Aqua fortis. In the sire it acquires an additional hardness, and a darker colour.

It is highly valued by painters and other artificers for its fine colour. It is faid to make excellent crayons, but not to mix with oil fit for painting. In medicine, it is of great use among the Germans. They use it for the same intentions as the Hematites, in all kinds of fluxes, as hemorrhages, dysenteries, &c. with success. It is said to have been the chief ingredient in the famous powder of Dr. Lehman, physician to the Elector of Saxony.

A friable, heavy, florid red ochre is dug among the fame rocks, It is of a friable uneven texture; of a rough and dufty furface; crumbles eafily between the fingers, and flains them very much. It melts freely in the mouth, of an aftringent tafte, and gritty. In water it makes an ebullition with a hiffing noise, and inflantly

moulders

moulders into a fine foft powder. It does not effervesce with Aqua fortis. In the fire it crackles a little, and acquires a confiderable additional hardness, and a paler colour. It is much used in painting.

A fine black clay-ochre, with a bluish-cast (1), is in a scar at the east end of the rectory-den at Simonburn. It is near the top, in a vein of about feven inches thick, under a stratum of limestone, and above another of grey and yellowish-white fand. Towards the middle are large heavy masses of friable freestone, and under them large flags. Many of the freestone masses lie scattered at the foot of this great fleep, tumbled down by florms and frofts, shattered and broken, shewing numerous impressions of the bark of refinous trees, of a tawney black colour. Many of the flags are deeply channelled by the dripping of the water; others fmooth and thick, of a great fize, not unfrequently two or three yards long, and as many broad; large pieces of fulphur in them as big as walnuts. This and the fand lie among them promiscuoully. The ochre with the least pressure between the fingers breaks into thin flakes or lamella, of a smooth glossy surface, unctuous to the touch, and flightly flaining the hands. It adheres to the tongue, melts freely in the mouth, of an infipid tafte, with very little grittiness. In water it makes a flight ebullition, feparates into fmall tabular pieces, and moulders by degrees into a fine powder, and gives it a bluish-black colour. Depurated, and worked into a paste, it cuts through with a glossy furface. Dry, it retains its colour, and drawn on paper or a board marks a line of the fame tinge. It does not effervesce

with Aqua fortis. In the fire it acquires a confiderable hardness, and a bright bluish-grey colour.

The Welsh, in Merionethshire, call it Nod dû, which in their language fignifies a black mark. They find it near the top of Cay Avon, a high hill near the village of Dynasmondhwye, in that county, and is on record in an old British proverb for being one of the three remarkable things of that place. They use it in marking their sheep. They prepare it by pounding it in a mortar, and moistening it with water, and then making it into balls.

It is very much used in painting by the Germans and Saxons. The former are said to find it at Dietsurterriet, in the territory of Pappenheim. They prepare it by carefully washing away the impure parts, and make it up into sticks or rolls like Indian ink. The latter call it, Schiefer Schwartz, and prepare it in like manner.

In our northern counties it is commonly known by the name of *Collow* or *Killow*; by which name it is called by Dr. *Woodward* and Dr. *Merret* (m).

A light, friable, gold coloured ochre, the ochre of *Theophrassus* (p), is found in concreted nodules among the *Geodes* and loose iron-stone on the edge of the brook at *Simonburn*, and other places in *Tynedale*, not unfrequently. It is of a lax texture, and of a dusty surface when broken, colouring the singers with a bright gold yellow, extremely light and fine, like an impalpable or farinaceous powder. It adheres firmly to the tongue, melts freely

in the mouth, pure, foft, and entirely free from grittiness. In water it raises an ebullition with many bubbles, and a loud hissing noise, but does not readily break and moulder in it to a powder. It does not effervesce with Aqua fortis. In the fire it acquires a little additional hardness, and an elegant storid red colour. Dr. Hill informs us, that he tried it as a paint, both native as a yellow, and burnt as a red, and found it exceed all the ochres the painters use in both these states.

A light, friable, deep yellow ochre, the Ochre Attic of the Antients (o), is also found in concreted nodules with the former. It is of a loose plated texture, of a dusty surface, colours the hands, and remarkably light and shattery, of a bright deep yellow, like that which saffron gives to water, sometimes lightly spotted with red: It adheres to the tongue, melts easily in the mouth, pure; and free from grittiness. In water it makes a great ebullition, but does not readily moulder away in it. It does not effervesce with Aqua fortis. In the fire it burns to a dusky red, without any hardness.

A heavy, friable yellow ochre (p) is frequently turned out in detached pieces by the floods on the fouth fide of the brook at Simonburn, with the geodes, and other flones and gravel. It is of a fine flrong yellow when moift, and of a dufty dead yellow when dry; heavy, and of a close texture, foft to the touch, and colouring the hands; adheres firmly to the tongue, melts flowly in the mouth, without grittiness; moulders or separates flowly

in water. It effervesces with Aqua fortis. In the fire it acquires a fine deep red, with very little additional hardness.

It is inferior in quality to the light ochres, but is greatly used in painting. It is the yellow ochre of the shops.

A friable, clayey yellow othre (q) is in a fear by the brook at Birch-Crook, near Shitlington-hall, in Tynedale, in a thick firatum, above another of black clay. Moift, it is of a dull dufky yellow, moderately heavy, and fhattery on being cut through with a fpade; foft in handling, and tenaceous; melts in the mouth with a little grittiness; raises a small ebullition in water, with a hissing noise, mouldering or breaking slowly to a powder. Depurated, and worked into a paste, it is of a clear strong yellow. It does not effervesce with Aqua fortis. In the sire it acquires a pale red, and a considerable hardness. It is used in painting.

A light, friable, faffron-coloured ochre (r) is frequent about the adits of many of our coal-mines, and chalybeat fprings. By the two fprings at Dibden, near Rothbury, it is in great abundance; half a foot, or a foot thick in some places, by the ditch-fides, made to carry off the water. We have it also plentifully on the strand of the rivulet by the coal-work at Simonburn, and in a small rill at Brunton-hall, near Chollerford-bridge, coating the stones, and other things in its way. It is of a light dusty surface, and extremely lax and shattery, soft to the touch, stains the hands, and melts freely in the mouth. In water it raises an ebullition, with a hissing noise, but does not break easily to a powder. It does not effervesce with Aqua fortis. In the sire it acquires a fair red. It is found in different degrees of purity.

<sup>(</sup>r) Ochra levissima slava friabilis. Hill. Hist. Foss. p. 52. No. 3.

A light, friable, deep brown ochre is found in the fiffures of a limestone-quarry at Bladon, near Belford, in considerable quantities. It is of a very lax texture, of a dusty irregular surface, soft to the touch, and stains the hands; adheres sirmly to the tongue, melts slowly in the mouth, of an astringent taste, with very little grittiness. In water it moulders and breaks slowly. Dry, it shews some few spangles of micæ. It does not effervesce with Aqua fortis. In the fire it acquires a deep reddish-brown colour, with no additional hardness. It is a fine species of umbre (s).

## CHAP. IV.

## OF SAND.

Great part of the Sand with us is very little regarded, and little used, except in masonry, though we have great varieties of it, and some not inferior to the valuable Tarso of the Venetians, with which they make their fine glass. This is our mountain or rag-fand. I will not fland to dispute, whether it is adventitious or natural, originated there. But I will declare what I have found true by experience. I had an inclination a few years ago to examine the inferior strata of one of our northern hills, the better to judge of the structure and phanomena of the earth, and for other reasons. This hill was lofty, conical, and rocky to the very furface, the fouth exposure covered with wood, hazel, and oak. I first cleared it of the wood, then began digging at the top downwards with a mattock and a spade. The space marked out for the experiment might contain about eleven yards in length, and fix in breadth. The earth and stones, as they rose, I cast down the southern steep, difrobed of its flourishing timber and shrubs. The first stratum. for about two feet, was a fine brown, loamy earth, wherein were feated an abundance of coarfe, hard pebbles, of the blue kind, commonly used in paving, so thick, as if a flood had cast them there; the next course, for the same depth, consisted of masses of red freestone, lying in light fand, in great confusion, and in great quantities, pretty large, of all shapes, some of them fplitting into excellent flags. These were succeeded by some of a vast magnitude, which I was forced to split with wedges. Under them was a bed of water-gravel, as good as any upon the fhores

shores of our rivers, and below it a bed of fine Tarlo, or mountain-fand, white, angular, and diaphanous, about a yard in thickness. On clearing it away, an amazing heap of other great ftones appeared in view, in all positions, some round, some spherical, one or two of these last nearly in a perpendicular attitude, of a vast fize, dreadful to look upon, seeming to threaten immediate destruction as I stood near them. They rested on a bed of water-gravel, under which was a bed of Tarfo, like the former. I digged no farther, my curiofity being fatisfied, believing that I should have found the like strata of stone, gravel and fand, to any depth. The diffection of this hill is a demonstration of a deluge or inundation of waters, and confirms the opinion of Herodotus, and other observing and valuable writers, that fuch a variety of strata of earth, of stone, of water-gravel, and of sharp rag-fand, in fuch different ranges and dispositions, can be attributed to nothing but a flood, the lighter bodies being uppermoft, and the heavier below them, by their own denfity and gravity. I found no land, river, or fea-shells of any kind, not so much as the molds of any. To try the fertility of the earth and fand, feparated from the groffer bodies of huge stone, and large gravel, I converted the fouthern declivity of this hill, now become pendent and floping, to a garden, walled the back and fides of the cavity, and the femicircular foot or bottom of the flope, with the stones. It proved very fertile, growing peas, beans, various plants and flowers, and from the warmth of the exposure, would undoubtedly have brought grapes to a tolerable perfection. It is sheltered to the north by its own lofty summit, to the east and west by towering oaks, and to the south by another shady hill extending in the same manner east and west, and between both is a fine trout-stream, crossed by a bridge in fight of one arch, with a vale also in fight through which it glides, adorned on each fide with banks of oak, and other forest-trees,

whose shade with the morning and evening-sun upon the waters, afford a very beautiful landscape. The fertility of the soil must be attributed to the deciduous leaves of the trees, and to the salts in the stony, arenaceous, and virgin-earths. I was about two winters, and as many summers, in seasonable weather, in the midst of very ill health, in digging this hill, and bringing it into the form described; and did not at first expect to meet with such irrefragable testimonies of a deluge, and least of all, this valuable sand. The crystalline rag stone of our mountains, heaths, and lakes, seem to be an aggregate of it.

On the shore of *Halypike-lake*, is a large area of rag-sand, the granules or pebbles small, no bigger than coarse *Smiris*, white, transparent, mostly angular, except some sew that may be blunted by attrition, and the agitation of the waters. In the lake, and on the heath round it, is an abundance of rag-stone, composed of the like crystalline sand or pebbles, glittering and shining, which are separated by being exposed to severe tempests, and by collision in the tumultuous billows of the lake. I have tried it in polishing marble, for which it is excellent, giving them a surface expeditiously. Farmers use it in giving an edge to their seithes.

There is a fand upon the shore of Coquet-island more bright and glittering than this, like such as is found about the Scilly-islands; being silvery, micaceous spangles of Talc, washed by the tides off large strata of talcy stone, very plentiful upon the shore between Warkworth and Aln-mouth, not always visible for heaps of sand, but often in view after high tides and storms.

Sea-fand, in many other countries, is greatly valued for mellowing sliff clay-ground, but in our's it is rarely minded, though the sea-coast is generally a clay from *Tyne-mouth* to *Berwick*. Providence

vidence feems to have ordered it fo, to incite our industry. Every tide, at certain feasons, casts up vast heaps of nitrous sands, and a great variety of shells, which feem to invite us to remove them, to fertilize our stubborn soils in our fields and gardens with their prolific salts. In that part of the coast, where there is no limestone, the neglect is inexcusable, and we cannot escape the charge of indolence, especially as the expence is easy, and it lies at our very doors in several places. Dristed sand is steril, and of no use, the salts being evaporated, or washed away with the rains. But such sand as is turned up by the tides after seasons, mixed with shells, would richly reward our labour. This sea-manure has been practised in the north of Scotland with great success for barley and oats, the seed producing some seventeen, and some eighteen fold, as has been attested by a curious and observing Scotchman, of excellent sense and veracity (a).

Our gardens might be greatly enriched with River-fand, being the lightest and richest of the meadow-soils, washed away with the floods, but few persons are at the pains of using it.

Ordinary fands, of various colours, we have in great quantities, but they are of no use that I know of, except in masonry, and in making garden-walks.

<sup>(</sup>a) Sir Geo. Makenzy, Ph. Tr.

## CHAP. V.

## OF STONES.

I T hath been observed, that the Fossilist is the subject of pleafantry with the witty and the gay,—

Rident vicini glebas et saxa moventem. Hor. Epist. l. 1. 14.

But this is only done in an hour of joy, and not in the moments of fober thought and reflection. All, but the stupid and inconsiderate, admire the useful and beautiful productions of nature, and confess the divine Wisdom to be as conspicuous in the structure and configuration of minerals and common stones, as in the ruby or the opal. Both more particularly strike the fossibility, whose attention is more immediately engaged than other men's. The subterraneous treasures appear before him in all their lovely variety, and their several beautiful orders; he beholds them with wonder, and considers them as incontestible evidences of a Divinity, and irrefragable constutations of atheism. Every pebbly shore, every quarry, as well as every field and grove, is to him as a temple, for praise and adoration.

Of Free-stone, valued for its common use, we have a great abundance; both in strata and loose masses, solid, and laminated.

The whitest I have seen in strata is at *Chapel*-houses, by *Benwell*-hill, composed of sine whitish-brown sand, and numerous silvery spangles of tale; is facil and condescending to the chissel, and hardens

hardens in the air. The quarry is large, and of a great depth. Masons are continually almost at work in it, hewing blocks of it, of all sizes, for sale.

A better fort, but not fo white, is in a quarry by a fmall stream, about two hundred yards east from the village of Denwick, near Alnwick; confisting of small whitish-brown sand, and silvery mice; of a close, compact texture, soft when taken out, and hardens in the air, works into any form with the greatest ease. It is used for chimney-pieces, and other ornamental stoneworks. This quarry is troubled with water, and has a roof of rubble and earth about three yards thick, which makes the working very expensive.

In a quarry at Stony-path, a mile west from Alnwick, near a wood, called the Stocking, is a whitish-brown free-stone, with mica, of a fine grit, and easier got, but less conformable and pleasant under the chissel.

At Berlin, near Warkworth, is a free-stone of an excellent quality for building, some of it nearly equal to the Portland-stone for colour and duration, of which large quantities have been lately wrought for rebuilding that magnificent fabric, the castle of Alnwick, by his Grace the Duke of Northumberland, and much of it carried off southward by export, for building a nobleman's seat near London, as I am informed. The roof has about eight feet of rubble and earth in some parts.

By the fea, near *Howick*, is a free-stone reckoned very good for building. It is of a more coarse grit than the *Berlin*-stone, and of a less bright colour. It is used for stone-steps, pavements, and other stone-works, bearing the weather well. The seat and

fine stables of Sir Harry Grey, of Howick, are built with it. The church of his Villa of Howick was also repaired with it by his late father, of his own name, after a handsome manner; an act of pious generosity that will ever reflect honour upon his memory.

There is a quarry of the fame kind by the fea at Bednel.

At Bladon, near Belford, is a whitish-brown free-stone, with glittering talcy particles, very good and lasting for ornamental works. The genteel seat of Abraham Dixon, Esq; of Belford-Hall, is built with it.

By Glanton-pike, a hill so called from its piked top, and the neighbouring villa of Glanton, near Whittingham, i. e. the town by the glen or valley, corruptly Glanton, is an excellent free-stone, of a brighter colour, and of a firm and close grit, many spangles of micæ in it, much used in ornamental works. The antient seat of Edward Rodham, of Rodham, Esq; was lately rebuilt with it.

At Etall is a good free-stone, but of a duller colour, with which the handsome seat of William Carr, Esq; is built.

At Camboe, near Wallington, is a free-stone of a fine grit, and of a bright whitish-brown colour, with splendid particles of talc, accounted excellent for chimney-pieces, columns, and other ornamental works. It has been much used in the genteel seat of Sir Walter Calverley Blacket, Bart. at Wallington.

A very good free-stone is at *Belsay*; of a close grit; of a dull whitish-brown colour, with silvery spangles of talc. It is used for columns and chimney-pieces; for which uses some pieces were lately wrought for the handsome seat of the Revd. Dr. New-

ton Ogle, at Kirkley. The feat of Sir John Lambert Middleton, Bart. at Belfay, feems to have been built with it.

By North Gosforth, near Newcastle, and at Acomb, near Bywell, is a whitish-brown free-stone, with glittering micæ, commended for ornamental stone-works; the Acomb-stone of the brightest colour, and closest grit, with which the handsome seat of William Fenwick, Esq; of Bywell, is built. With the other, the sine seat of Charles Brandling, Esq; of South Gosforth, is built, both designed by Paine; as was Belford-Hall.

By the fea, near Seaton Delaval, so called from the town or villa by the fea, and the local name of its antient baronial possessors, the Delavals, is a free-stone accounted excellent both for colour and duration, of a whitish-brown, with splendid micaceous particles. That grand structure, the feat of Sir Francis Blake Delaval, Knight of the Bath, of Seaton Delaval, was built with it; designed by Sir John Vanbrough.

On the north fide of a small stream, called Spital-burn, from its course by an antient hospital or elemosinary, near Newbiggen by the sea, is a free-stone of a dull whitish-brown colour, of a coarse grit, with silvery micæ; of great mechanical use, both for building grind-stones, and sire-stones for the glass-houses; the stratum, in parts, now worked, about eight feet, the roof at the highest about ten feet, chiesty a red clay; near the eastern point very little roof, the stratum twelve feet. There is a stratum of the same stone on the south side of the burn, six feet thick; the roof about as much.

By a streamlet called the *Den-Burn*, on the east side, near *Assimpton*, is a free-stone of the same grit and colour, worked for the same uses; the stratum of a great thickness; the roof about Vol. I.

I twelve

twelve feet. The river Wansbeck glides past it in a full and beautiful stream; on the south side of which is another quarry of the same kind, not worked on account of the weight of the roof. From the Spital and Ashington quarries many thousand grindstones have been exported.

In the brook at Simonburn, between Tecket and the rectory-den, are vast rocks of free-stone; fallen from a range of steep cliffs above, used much in that neighbourhood for tomb-stones; of a whitish-brown colour; of a close fine grit, with shining talcy particles; small Neuclei or kernels in part of it, with casts of reeds, and barks of trees. Their tops are coated over with a stratum of adventitious earth, the decidua of leaves, moss and herbage, rotted to a mellow compost, giving nourishment to a variety of plants; Vaccinia nigra, Ericæ, and the Sorbus aucuparia, slourishing with great vigour, and mosses of a beautiful green fringing their sides, unhurt by torrents and tempestuous winds.

On Broad-pool common, near Simonburn, is a range of steep free-stone rocks, with a north exposure, called Raven's-bugh, i. e. the Raven's-Crag, from its being the solitary and secure retreat of that bird by its high situation, and scraggy projections. It is mostly in horizontal strata, with some large perpendicular sissures, as is usual in precipices. It is of a whitish-brown colour, with silvery particles of tale, and of different degrees of sineness; part of it making excellent grind-stones; the greatest part highly esteemed for pavements, stone-steps, columns, and ornamented Ashlerworks. It holds its colour and form under the rigour of the severest seasons. The handsome seat of Sir Lancelot Allgood, of Nunwich, Knt. is built with it, designed by Mr. Garret.

At the west end of the crag is a spring, under a scraggy cover of natural arch-work, the sides in summer shaded with dwarf stone-

flone-ferns, the adit flored with that wholesome and agreeable fallad, the water-cress.

Near this fpring are the ruins of huge rocks, beaten down by storms. One is fifteen feet long, eighteen feet and sifteen inches broad, and above six feet thick; the black Mane Usnea, or rockhair, on the back part of it. Another, by the violence of the fall, has started from it, and rests with one end at the bottom.

At a fmall distance eastward, is a third of a more remarkable fize, one solid mass, twenty-seven feet, ten inches long, eight feet broad, and twelve feet thick; *Vaccinia nigra*, and *Ericæ*, on the top.

By the village of Fenwick, near Kiley at Ancroft, and Norham, near Berwick, is a free-stone of a pale red colour. With the Fenwick-stone, the priory of Holy Island seems to have been built; and with the Norham-stone, the castle of Norham.

On White-fide bank, near Wooler, is a free-stone of a light purple; of a close grit, with some talcy spangles; the stratum three feet, and the roof six feet, thick.

I might mention fome other quarry-free-stones, but these are of principal note for mechanic uses.

The whitest and most beautiful free-stone found in detached or loose masses, is on the estate of William Swinburn, Esq; at Long Witton, near the village, composed of a bright white sand, and silvery micæ, laced with sparry veins, which render it less condescensive to the chissel. It is used for chimney-pieces, and other ornamental stone-works.

At Shilden, near Corbridge, are digged up large masses of free-stone, of a coarse grit, with talcey spangles, of a whitish-brown colour, accounted excellent for grind-stones, gate-posts, and other excomenical uses.

Quarries of rag-stone, sit for mill-stones, are scarce. The best for that use are on the west side of Blalack-burn, above a bridge of one arch, near Wyden-Eles; the stratum nine feet thick, under it a coarse slate, and above it nine feet of rubbish. The master-quarrier for every pair of mill-stones pays to the proprietor 1.1. 10 s. They are conveyed for their goodness into remote parts of Scotland.

Near a lake or lough in *Coenwood*-forest, three miles east from *Knarefdale*, is another mill-stone quarry, of good esteem; the strata appearing at the very surface.

On Bewick-common is a mill-stone-quarry of good note; also one near Harbottle; and another near Rothbury-east-mill.

Above the water-fall at *Tecket*; near *Simonburn*, are huge detached masses of rag, of the true mill-stone grit, but not used. The top of one rock has been cut into a mill-stone form, but deserted for its hardness.

Nodules of fine rag, commonly called moor-stone, lie scattered in great plenty on the brow of *Calleley-Hill*; in frequent use with countrymen for whet-stones to give an edge to their scithes.

Masses of coarse rag, composed of arenaceous and talcy granules, and quartz-pebbles, from the size of a pea to a nutmeg and a walnut, lie dispersed on *Fourstone*-hill, near *Hexham*. The garden-walls of the *Eremite*-convent at *Hexham* were built with this kind of stone.

Large masses of fine rag, fit for building, are common in many places. Our ancestors have chosen to build their fortresses and strong holds, and the Romans their castra, with it, as best enduring the rage of time and the weather. The castles of Bambrough, Dunstonbrough, and Prudhow, are built with it; the mortar of Bambrough-castle composed of lime, sand, and sea-shells, chiefly the small white Turbo, not the least decayed in the course of so many ages.

Laminated free-stone, of a good quality for slags and slates, is plentiful. At High Moralee, on the edge of Gofton-burn, near Wark, in Tynedale, and at Bromehope, in Reedsdale, is a slate of a purple colour, of a fine smooth surface, thick fet with glittering slakes of micæ.

At Low Moralee, by Gofton-burn, are good grey flags and flates; fome strata of both curiously figured; of which hereafter.

At Bay-Bridge, in Hexbamshire, and at Birtley, near Chipchace, and at Black Heddon, also at Bolham, is an excellent brown slate. They have the valuable properties of hardness and lightness, not easily pervaded by water in the most rainy seasons, or parting into shivers under the severity of tempests and frosts.

There is also a brown slate of good note at the bottom of two remarkable cliffs of free-stone by *Haltwesel*-burn, near *Lee's Hall*, at a small distance from the military road. The cliffs project into the rivulet east and west; the streams winding under them in pleasant murmurs; their broken sides shaded with brushwood of various kinds; near them a chalybeat spring.

There is a very good brown flate at Great Whittington, Acome, Buteland, Halywell, Rothbury-East-Mill, Halystone-Fell, Barrow, Folbury,

bury, Etall, and at Stony-path, near Alnwick. Their furfaces are all, more or lefs, fet with fplendid talcy particles, which pafs the fire without losing their lustre, at the same time that the slate crackles and bursts into shivers, or loses its natural colour.

In the grounds at Overton, near Simonburn, on the estate of Sir Ralph Milbank, of Hannaby, in Yorkshire, Bart. is a flate of a bright lead-colour, their furfaces extremely fmooth and shining with filvery flakes of tale, the laminæ distinguished at the edges by alternate deep blue, and ochreous yellow veins; the firatum fourteen inches and a half thick, faced with an irony, rufty-coloured flone, which, on being flruck with a hammer, falls off like wooden laths. Above and under the flate is a large flag, each from four to fix inches thick, dipping to the fouth, and rifing to the north; fome of the bottom-flags of an irregular and uneven furface, as if bulged and bruised with the weight of the incumbent roof. The roof is in some places eighteen, and in others twenty-four, feet. The flags are used for tomb-stones, and look very handsome under cover, but are too tender to bear the weather. They may be had of a very large fize. Both the flags and flates are impatient of the fire and frosts. In the fire they crackle, and burst with a loud noise like the report of a pistol, owing to their fulphurs. Under the feverity of frosts and tempefts, they feparate into thin leaves or plates, and moulder away. If the flates had hardness equal to their lightness and beauty, they would be the most valuable of any in the kingdom for covering houses. There are some few, indeed, in the same quarry of another nature and colour, of a hardy ferrugenous constitution, and of a rusty hue, not altering by the torture of fire, or by heavy rains, and piercing frosts. These are used by the country people in the neighbourhood in the structure of their flew-ovens.

Free-stone is frequently found curiously figured, both in detached masses and in strata, of which the following are the most remarkable that have fallen in my way to collect.

A whitish-brown mass, in the form of half an *Ionic* column, twelve inches long, and twenty-three inches over, with numerous digitated figures on the surface in relief, in a quincunx order, of about three quarters of an inch in length, and half an inch in diameter at the base, gradually tapering to a rounded point; the under side scraggy and uneven; some of the scrags struck off to make it portable. From a quarry in *Rothbury*-forest, near *Simonside*.

A piece of a small flag with a curious representation of a plant in relief, with a bold stem and branched; the branches dactyliformes.

Another piece with four finger-like shoots from one root, in bold relief likewise. These are formed by the infinuation of water and sand between the lamina. A marble rubbed down to a smooth surface on a wet stone, and taken hastily off, will shew arbuscular sigures of its own grit, sometimes like a forest, in relief.

Part of a flag, channelled, with elegant wavy ftriæ at the bottom of the channels, uniformly fulcated in the middle, through the whole length. One of these ftriæ takes a doubling course of twenty inches, beautifully serpentine.

These three from a free-stone quarry on the edge of the brook at Simonburn, below the school-house.

A large, thick, brown flate, with broad, transverse, parellel channels, the intermediate spaces turned or swelling in half rounds, very beautiful. From a slate quarry on the top of the wood at Con-sheels, near Wark, in Tynedale.

In the flate-quarry at Low Moralee, are three courses of a dark brown flate, thick set with arenaceous cylenders of a light brown, of the fize of a goose-quill.

In the fame quarry is a course of light grey slate, with numerous irregular blotches of black, of various sizes.

There is also in the same quarry a course of a large, brown slag with thin lamina on the surface, resembling the waves of the sea, very beautiful.

Nodules of reddish-brown free-stone, with true Stalagmitæ, or crustated bodies, including one another, like cups, are frequent on the shore of the brook below Simonburn-castle.

On the shore of the river *Coquet*, below *Welden*-mill, I gathered a nodule of whitish-brown free-stone with many longitudinal parallel lines of a dark brown, like the veins or crusts of pebbles. It is formed, like them, by incrustation.

Whet-stones, for the finer tools, are rare. There is an approved fort, of a dark greyish-blue colour, found on the strand of the brook by Setling stones, above Newbrough, near an old deserted leadmine. These are of so sine a grit, that they will give an excellent edge to a razor. There are rocks of a plated stone on the edge of the brook, out of which these are washed by the sloods, but a long search may be made before a good one can be picked

out; the largest not above twelve inches long, and six inches broad. Mechanics are very fond of them.

On the edge of the brook at Swinburn-castle, above the mill, is a plated rock, of a light greyish-blue colour, and exceeding sine texture, from which I have had whetstones that give a very good edge to penknives. They are also scarce. Small masses are sometimes found lying on the pavement of the brook below the mill, turned out by floods; the longest not above fourteen inches, and sive or six inches broad. There is a variety of it of a softer texture; very much used in that neighbourhood within doors for giving a white stone-colour to chimney-pieces and hearths.

In the grounds of a farm, called *Black-Carts*, near a gate leading to *Newbrough*, from the military road, is a laminated flone of a light grey, and also of a dark blue colour, of great use to shoemakers in giving an edge to their knives, for cutting leather. It is also used in writing-schools for pencils, for the *Irish* state, drawing a white line freely. That at *Swinburn* is frequently put to the same use.

Quarry-marble, or marble found in strata, is not uncommon. A fine fort was lately discovered on the estate of Sir John Lambert Middleton, of Belsay, Bart. by a farm, called the Park-House. It is of a grey colour, with streaks of black, thick set with that large, scarce, and beautiful coralloid, the Alcynoium of Mr. Edward Lbwyd, said by Sir Hans Sloane to be a native of the American seas, (a), of a whitish-brown colour, lying in all directions (b). It is of a fine texture, and great brightness, rightly polished. It rises in large blocks, ten or eleven feet long, sive or six feet

<sup>(</sup>a) Ph. Tr. No. 257.

<sup>(</sup>b) Marmor coralliticum, durius, cinereo nigrescens. Hill. Hist. Foss. 472. No. 1.

Vol. I. K broad,

broad, and two feet thick. It is used, at present, only for lime, but when its value is better known, it is likely it will be preserved for such ornamental mechanic uses, as it deserves; being only discovered early in the year 1766.

Near Dilfon is a dark blue marble, shaded with brown, refembling Jasper, taking an elegant politure. There is a table of it at Corbridge cut and polished by the owner, Mr. Lumley, an ingenious stone-cutter, from London.

By the village of *Corbridge* is a light blue marble, thinly fet with fmall *Entrochoi*, which being white make a pretty variegation. There are tomb-stones of it at *Halton*, and a mural one erected over Dr. *Rotheram*, a differing minister, in the church at *Hexham*. This has a brown shade. It is bordered with a molding of black marble from a quarry at *Frosterley*, near *Wolsingham*, in the bishoprick of *Durham*, thick set with white coralloid *Fungitæ*, in all directions (c); rendering it very desirable for chimney-pieces, slabs, and tables, frequently polished and sold for that use by the *Corbridge*-artist, whose workmanship these sepulchral marbles were, enduring the weather tolerably well, but losing their lustre, and doing the marbalist little credit, when long exposed.

At Chefeburn-Grange, near Stamfordham, is a marble of the fame colour, prettily variegated also with white Entrochoi, admitting a neat politure. There is a mural sepulchral stone of it by the south end of the altar-table in Newburn-church, erected to the memory of Mr. Longridge, of Wallbottle.

<sup>(</sup>c) Marmor nigrum coraliis refertum. Da Costa. Hist. Foss. p. 232. No. 73.

In Callege-park, near Alnwick, is a blue marble with the fame variegations, conforming with difficulty to the chiffel, yet taking a tolerable polish. It rises in blocks of four, sive, and six feet in length, of different thickness, from nine to sixteen inches.

On Long Houghton-moor, about a mile north-west from Ratsbugh, and near a mile from Denwick, is a dark blue marble, easily worked into any form, and of a pleasant politure. It is raised in masses of seven or eight feet long, and generally about nine inches thick.

About a mile from Witton, near Rothbury, is a light blue marble, of a fine texture, and capable of a neat politure. There is a mural fepulchral stone of it in the chancel of Rothbury church, over the remains of Dr. Thomlinson, rector of that parish, the polishing part poorly performed, smooth and even, but of no lustre.

At Fair-show, near Nunwick, is a blue marble, thick fet with madrepore-coralloids, composed of a bright white opake spar of the fize of a goose-quill, the ends in their Cuticulæ, or rough coats, looking like the subterraneous vermicular vagrants, rising in succession, and in crowds to make their exit. Polished, they shew their interior texture, many of them radiated from the centre, with annular circles; the marble appearing with them very neat and handsome. Some part of the road above Fair-show is paved with it; several fragments now lying upon the surface (d).

<sup>(</sup>d) Marmor subcæruleum. Da Costa. Hist. Foss. 198. No. 17.

Marmor subcæruleum splendidum, durius, quod Marmor Numidicum antiquorum. IIill. Hist. Foss. p. 465. No. 1.

Pierre bleue, Blaeuwe stein. Boccone Rescherches et Observat. Nat. Lett. 13. p. 124.

These marbles are used for lime, as well as the *Belfay*-marble, whereby some of them are become scarce, particularly the fine sort at *Dilston*, and the *Callege*-park marble.

From our River, and Sea Shores, I have been furnished with the following Marmorites, or small masses and nodules of marble.

- regularly fet with many columns of coralloids of the fame kind with those in the *Belfay*-marble. They all lie parallel to the furface, and look like an affemblage of *Auricula* pips in their natural colours, giving the stone an extraordinary beauty. From the shore of the brook at *Simonburn*, below the school-house. Turbinated and bivalve sea-shells are frequently found immersed in it; of which hereafter.
- 2. A marmorite of a deep red colour, with coralloids of a bright red, of the fize of a fixpenny flick of fealing wax, in a perpendicular order, parallel to the furface. From the fhore of the brook at *Gofton*.
- 3. A marmorite of a reddish-brown colour, with coralloids of a bright and beautiful orange-yellow, of the size of a large goose-quill; the tubes silled in the center with a bright white spar, like small points or specks, adding much to its beauty.
- 4. A reddish-brown marmorite with small coralloids of a bright white, filled with a substance of the same colour with the stone.

These two from the shore of the brook near Nunwick.

A greyish-brown marmorite, thick set with coralloids of a bright grey, of the size of a goose-quill, with a white annular circle, and a white apex in the centre. From the shore of the brook

brook at Simonburn. We have this kind with coralloids of a bright white; also bright white with a blush of red (e). Turbinated and other marine shells are frequent in it.

- 6. A black marmorite with coralloids of a yellowish-white colour. It is of an oblong shape, of about a foot in length, and half a foot broad. From the same shore (f).
- 7. A grey marmorite shaded with an orange-yellow, and thick set with small coralloids of a pearl colour, and transparent; numbers of them in relief upon the surface, resembling worms, as if alive and crawling. It is the Marmor junceum of Dr. Woodward (g). From the shore of the brook near Simonburn-castle. It is also frequent on our other shores, and on the sca-strand; of a considerable size, sometimes large enough for small tables, chimney-pieces, and other ornamental works.
- 8. A marmorite of a deep purple colour, with coralloids of the same kind, of a bright and beautiful orange-yellow, of the size of a crow-quill. From the shore of North Tyne, below Chipchace-mill, by the Strother-house.
- 9. A marmorite composed of numerous fragments of seashells, in so consused an order as not to be distinguished, forming a most beautiful variegation, in parts resembling slowers; the brims of a fine chocolate colour, the eyes of a bright orange.
- (e) Marmoroides cinereus coralliis refertus. Da Costa. Hist. Foss. p. 247. Woodward. Cat. Foss. k. 17.
- (f) Marmoroides niger coralliis refertus. Da Costa. Hist. Foss. p. 244. Woodward. Cat. A. e. 27, 28, 29.
- (g) Marmoroides susco-cinercus coralliis resertus. Da Costa. Hist. Foss. p. 248. Wood-ward. Cat. A. e. 22.

It is the *Blumenstein*, i. e. the *Flower*-stone, of the *Germans* (b). From the shore of the brook below *Simonburn*-castle. I found a variety of it on the same shore, which I broke, and took out a small thick *Conch*-shell, and a small *Turbo*, entire, in their natural colours, white, with a tinge of red.

- 10. A greyish-black Marmorite with numerous fragments of white turbinated shells, the edges of some, and the *Volutæ* of others conspicuous, forming an elegant variegation. From the *Ostium* of *Goston*-burn, near *Wark*, in *Tynedale*.
- nents of fea-shells, of a bright orange-yellow, forming a large and beautiful figure, like a wreath; small pieces of entrochi thinly scattered on the surface, of a bright white colour. The wreath, or laureated figure, goes through the whole stone, fair and confpicuous on both sides. From the shore of a streamlet on the north-side of Simonburn-castle.
- 12. A greyish-brown marmorite, thick set with small entrochi, of a bright white, lying in various directions, the sides of some, and the ends of others appearing, forming a most pleasing variegation; from the shore of the brook below Simonburn-castle, where at this time is a very large mass of it among a heap of stones on the south-side of the ford (i).
- 13. A marmorite of a chocolate-ground, with fmall zones or circles of a light and deep green, very beautiful. From the fame fhore.

<sup>(</sup>b) Bruckman. Epist. Itin. Cen. ii. Epist. 26. p. 246. No. 29. Da Costa. Hist. Fost. p. 238.

<sup>(</sup>i) Marmor fusco-cinereum entrochis refertum. Da Costa. 235, 236. Woodward. Cat. A. x. b. 61.

- 14. A marmorite of an olive-green ground, spotted and varie-gated with a florid and deep red. It is a beautiful stone. From the shore of *North Tyne*, by the *Strother*-house, near *Chipchace*-mill.
- of various colours, brown, red, purple, and cinereous with purple friæ, forming a beautiful variegation; held together by a reddifh-brown cement. In its native flate in the earth it has an investient crust. From the shore of the brook below Gofton, where it is not unfrequent. I have a variety of it composed of smaller pebbles, brown, red, and yellow, from the shore of the brook below Nunwick-garden, large enough for a small table.
- 16. An alabastrine marmorite, composed of flat plates, laid evenly and closely upon one another, approaching to parallellopepid figures, of a yellowish-white, bright and pellucid. It is of a shattery texture in the mass, easily breaking into pieces of different fizes; some of the larger pieces elegantly striated lengthways, like the molding of a cornice. From the limestone-quarry at Fourstones, where it is frequent. It was the Marmor Phengites of the Antients (k), who had it from Cappadocia. They used it much in their public buildings. The famous Temple of Fortune, which had not a single window, was built with it, and was perfectly light from its bright transparence, in which consists its beauty. In works that do not require strength, it is very sine and ornamental, taking an excellent polish.
- 17. A marmorite of a fibrous texture, with beautiful veins, and radiated circles, of a flesh-colour; some of the circles varie-

Marmor phengites Plin. 2. p. 752. Cafalpin. p. 95. De Boot, 490, & 520.

<sup>(</sup>k) Alabastrites lucidissima, frustulosa, albido-slavescens: quæ marmor phengites antiquorum. Hill. Hist. Foss. p. 490. No. 2.

gated with a purplish-red, under a thin cuticula, or crust of the same colour, part of which is taken off by politure to shew its elegant structure and beauty, the variegated circles very much resembling small flowers. From the shore of the brook below Simonburn-castle.

- 18. A marmorite composed of fine capillary filaments, lying in various directions, some of them forming beautiful dendrita, or arbuscular figures, of a fan-like shape, of two different degrees of purple, with a slight tinge of orange and carmine; capable of an excellent polish. From the shore of the brook at Goston, near Wark, in Tynedale.
- 19. A marmorite of the fame structure, of a grey colour, of two different degrees; the friæ forming a large radiated figure at one end, resembling the rising Sun. From the shore of the brook at Simonburn, near the school-house.

We have a variety of it with transverse semicircular fillets, of a light grey, on a dark grey ground. It is more frequent without these elegant figures, yet very beautiful, the ends of the filaments forming a curious reticular work; its general colour grey, lighter or deeper, and sometimes of both these colours, in clouds and variegations.

20. A marmorite formed of a congeries of astroite coralloids, of a button-like shape, of a greyish-black colour, with black mashes. From the shore of *North Tyne*, opposite to *Kirk-field*, near *Wark*, in *Tynedale*.

These marmoreous Fibrariæ all ferment violently with acids. They are of a marine origin, and are commonly found entombed

tombed in stone, with madrepores, fungitæ, entrochoi, and testaceous bodies.

21. A marmorite composed of large coralloid pori, with fine, thin, longitudinal plates, in a stellate order, from the axis to the circumference, intersected by numerous transverse septa or diaphragms; the ends of the columns concave; a prominent flar in the center, with a fmall apex or point; three quarters of an inch in diameter; the interior colour a dark brown, and a yellowish-white, in a beautiful variegation; looking after politure like an affemblage of auricula-pips, appearing on all fides of the mass in a distinct and elegant disposition. It is a foot long, and half a foot thick. It was turned up by the spade in trenching Sir Lancelot Allgood's garden at Nunwick, near the brook. It is fometimes found, but rarely, on the fea-shore, by Ross-Links, near Belford, from which I had a fmall mass worn and smoothed by the tides. It is the great Lithostrotion of De Boot and Wormius (1), and the Alcynoium of that eminent lithogist, Mr. Edward Lbwyd, keeper of the Ashmolean museum (m). It takes an excellent polish. Mr. Lhwyd found some of it in Wales, but he does not tell us where, incorporated in limestone, not exceeding fix, nine, or twelve inches in diameter, preferable, in his opinion, to the Florentine marble. He has published a neat print of two pieces, one polished perpendicularly, and the other horizontally (n). The ingenious and curious naturalist Mr. John Beaumont, of Stoney-Easton, under Mendip-hills, in Somersetshire, who proposed obliging the world with a natural history of that county, if he had

<sup>(1)</sup> Lapidis astroitidis sive stellaris primum genus. De Boot. de Gemm. et Lapid. 1. 11. Worm. Museum.

<sup>(</sup>m) Ph. Tr. No. 252.

<sup>(</sup>n) Ibid.

met with due encouragement, presented Sir Hans Sloane with some pieces as fine, found on those hills. It is accounted one of the most elegant coralloid pori in the world.

22. A marmorite composed of *lesser* coralloid *pori*; the stars variegated with a light and dark grey, with white apices; the mashes white. From the shore of the brook at *Simonburn*. It is the *lesser Lithostrotion* of authors (0).

Of this leffer species we have a great variety with respect to colours.

if. With grey stars, variegated with black; the mashes of a bright white, undulated at the edges; the columns of the size of a common writing quill. From the same shore.

2dly. Of a dark brown, variegated with black. From the shore of the brook below Nunwick.

3dly. With deep red flars, encircled with a light grey, with numerous minute red fpots, on a grey ground, forming a most beautiful variegation. From the shore of the brook at Goston.

4thly. Of a deep red; a reticular work of small chrystals on part of the surface. From the shore of North Tyne, below Chollerford-bridge.

5thly. Of a florid red, very fine. From the fame shore. It is frequently found of a pale red on the shore of Warks-burn, above Crook-bank in Tynedale.

(0) Lithostrotion, sive basaltes minimus striatus et stellatus. Lhwyd's Lithoph. Britann. Ichnogr. Epist. 5. Tab. 23.

Marmoroides columnaris stellatus, Lithostrotion dictus. Da Costa. Hist. Foss. p. 246. No. 11.

6thly. Purple, variegated with an orange-yellow. From the shore of the brook at Gofton.

7thly. Of a bright fearlet; the mashes like fine lace-work; the heads of the coralloids resembling in their compartments the scarlet tubercles of the cup-moss. From the shore of the brook below Simonburn-castle.

These all have reticular ridges, and prominent stellar striæ in their perfect state, before they are worn and smoothed by the currents; and the red kinds commonly have a congeries of small chrystals on some part of the surface. Those that have their tubes silled with a red substance, and are tinged with the same colour, have sometimes an investient, stellate crust, very beautiful. Such incrustations are not unfrequent on rubble-stones, in which small masses of coralloid pori are sometimes included, very sine. Nodules of free-stone are sometimes found on the same shores composed of columns, and have small apices in the center of the masses, but have no stars.

Coralloid-marmorites, both with large and with fmall, concave stars, variegated with a light and dark grey, are frequent on the shore of the brook at Simonburn, above the bridge, turned out of the banks of blue clay, which abound with marine remains. Those with large stars are sometimes found with their columns in relief on the under side; of which I have a very sine specimen, in its argillaceous livery. They are both capable of an excellent polish, and may be had in large masses.

Marble has fpar for its basis, and ferments with acids. Calcined, it is said to yield a *Phosphorus*, which being held one minute in the light, becomes luminous when removed into a dark place. It is not fusible per se.

A variety of the coralloid species, with deep pori, composed of arenaceous granules, and small crystals, incapable of a politure, when rubbed down, is not uncommon on the eastern shore of North Tyne, by its Offium; and also on the shore of South-Tyne, but more rarely; the pori of the latter often extending near the whole length of the columns, glittering with corpuscles, or spangles, of crystal.

These astroite coralloid *Pori* are formed so much like a *Honey-comb*, that they have obtained the name of *Honeycomb*-stones.

Single columns of madrepore-coralloids, both cylindric, and branched, of various fizes, are not unfrequent in the clay-banks by the brook at *Simonburn*, above the bridge, on the north fide.

Of the former species, I met with a remarkable variety; grey, of a solid and firm texture, striated lengthways, a little inslected and compressed, with a broad furrow, towards the extremity, with white arbuscular striæ on a grey ground from the center to the circumference. It is an inch long, and as much round, the compressed end broken off.

Also of the other I met with one as remarkable; tuberated at the ends, with *Tubera* on the surface, and numerous minute *pori*, forming an elegant reticular work of a bright white on a black ground; the tubes filled with an indurated argillaceous earth, of a greyish-black; transverse alternate striæ of black and white from its edges to the circumference. It is found of different sizes, from a quarter of an inch to half an inch in diameter, and an inch or more in length, filled with indurated clay-earths of different tinges. It is so tender in the strata, that I have never been able to take it out with the branches entire, yet, when it has been exposed to the air, grows as hard as a marble.

Arbufcular columns are fometimes found entire in the Lamina of fhattery limeftone on the shore of the brook below *Simonburn*-castle; from which I had a small mass with some very fair.

Of the coralloid, called, Mycetetes, from its being composed of fine thin Lamella like the gills of mushrooms, we have an elegant species of a conoid shape, with transverse strike from the center to the circumference, forming a figure like the Sun. It is a beautiful object, white, sometimes with a tinge of red. It takes a high polish, and sometimes by including in the middle, part of the dark-coloured slone it is found immersed in, it forms a figure on the other side like that opake body the Moon, very striking to the beholder, expecting no such thing as a lunar representation on the reverse of a solar one. It is found from six inches and a half to three inches and a half in circumference at the thickest end, and from sive inches and a half to two inches and a half in length, in a black calcarious stone on the shore of the brook at Simonburn.

We have a variety of it of a compressed form, with transverse, undulated wrinkles, and a deep furrow on each side lengthways; two radiated sigures at the ends, resembling two Suns in miniature, the glory in light grey circles, on a dark grey ground. It is two inches and a half round at the thickest end, two inches at the smaller, and an inch and a half long. It seems to be two Fungitæ united together, there appearing by the help of a magnifier a kind of a slaw between them, not discernible by the naked eye. I had it from the bottom of the same river.

A Mycetetes with a large kind of Plexus or net-work in the center, with white firix on a pearl-coloured ground extending from it to the circumference, is sometimes found in limestone in the quarry at Cheseburn-grange, near Stamfordham, from which

I had it. It is composed of fine spar, and takes a neat polish. It is of a conoid shape, and a little incurvated; three inches and a half round at the thikest end, two inches at the smaller, and an inch and a half long; the small end holding part of the stone, of a yellowish-grey. It is sometimes sound double that length, in that quarry, tumid in the middle, and gradually tapering at each end.

On the shore of South Tyne, near Allerwash, in a calcarious stone, I found a group of them, lying horizontally, of a yellowish white.

I have also a fine one from the shore of the river Tweed, near Cornbill, found loose, of a reddish-white.

Of this kind, I met with two remarkable varieties; one of a conoid shape, with an arbuscular delineation in the center, of a bright white, on an ash-coloured ground; another of a flat form, marked with the capital letters I R in the center, of a bright white, on a deep purple ground; both struck out of a calcarious stone on the shore of the brook at Simonburn.

It is fometimes found in stone on the same shore with white strix, on a ground of two different degrees of purple.

On the fea shore by Ross-links, near Belford, and on the shore near Widdrington, a yellowish-white mycetetes is frequent in small masses of the marmor junceum, and other stones.

Innumerable quantities of a grey mycetetes are in the clay-banks by the brook of Simonburn. In my fearches for them, I have observed them frequently lying in great order, appearing as if jointed, till I have been undeceived by taking them out,

and found them fingle, in a linear position. The floods often turn them out of their argillaceous nidus's, and smooth their surfaces, when their transverse and longitudinal striæ are seen to great perfection.

Their most usual shape is conoid, but we sometimes find them of an irregular shape, and scyphiform, or cuped, like the cupmushroom, with sine striæ in alternate ridges and surrows, from a protuberated center in the cup to the circumference, and also length-ways. I have one of these of an inch and a half in diameter, an inch and three quarters long, and sour inches round; found in the bottom of the same brook, with a small conoid cuped mycetetes, with the same kind of striæ in the cup, and other larger striæ round it.

We have them also in stone on the same shore of a button-like shape, with an obtuse reflected apex underneath, of various colours; of a light and deep ash-colour; of a pearl-colour, with a beautiful blush of red; of a deep purple and white. They take an excellent polish. It is not uncommon to find this and the conoid species entombed in large loose masses of a greyish-black hard stone, in company with the grey and white undulated lithostrotion, entrochoi, and bivalve shells, great and small, in a most amazing confusion.

All the coralloid class are of a marine origin, the marmoreous casts of sea-coralloids, composed of longitudinal and transverse lamelle, so thin, as to form the beautiful radiated sigures described. Sections of them cut through both ways give a good view of their interior structure. They calcine to a white lime.

Of the figured stones, called Belemnitæ, or thunderbolts, the Trochitæ, Entrochoi, Asteriæ, or star-stones, composed of talc and spar,

fpar, with an admixture of fulphur, we have a great abundance. The largest and fairest I have seen are in the strata of clay above the bridge of Simonburn; where they lie in all directions, foft and fragil, not enduring to be touched but with the greatest gentlenefs, yet, when exposed to the air, acquiring the hardness of a marble, and capable of a politure. Their exterior colour, when washed and freed from the clay, is grey, or a yellowish-white. Sometimes they have an elegant indented incrustation, and fometimes an incrustation with minute protuberated points, of a greyish-black; both the indentings and points numerous. They are filvery and glittering when broke. Some of them exhibit a curious phænomenon by politure, the grit of one appearing very white, and that of another of a dark lead colour, inclining to black, owing to metalline admixtures. The radiated heads of others being taken down by politure, they exhibit beautiful clouds of grey and white, owing to the fame cause. In the fire they crackle and burst, shewing their glossy foliaceous texture. Rubbed hard upon a ftone they fmell like burnt horn. Their firia, from the center to the circumference, are formed to hold their joints together like futures. Their central tubuli or perforations are filled with various matter, as hard as their own fubflance, and of different colours, taking their interior figure and circular channels.

The Belemnitæ are of all fizes, from less than an inch to ten inches; some of them cylindric; others compressed, with a longitudinal furrow on one or both sides; some with small tubercles; and others with their joints a little raised. They are rarely found conic, and those not exceeding two inches in length.

The Entrochoi are from lefs than half an inch to fix inches, but it is with difficulty they can be had entire of fo great a length;

the intermediate ones most beautiful; some with their joints elegantly serrated, forming wavy lines, with a punctated surface; some with Appendicule, or radiated studs and branches; some with oval, and others with round hollows on their sides, like cups, as if they were the sockets of branches; some like screws, and therefore called screw-slones; some of those siner and thinner edged, and others blunter and rounder, with sewer circles.

The Afteria, or star-stones, are from less than half an inch to two inches in length. Some of them are perfect Intaglia, and may serve for seals. They have not all the like number of angles, nor are all the angles acute. Some of the stellar cavities are silled with a black, and others with a red substance, which on a white ground look very beautiful. Some of them have a single order of rays, and others a double one, encircling the stars; the latter order generally higher, and more raised next the brim. Some of them have elegant red wavy lines running through their white substance.

That beautiful species of Asteria which forms a stellar sigure like the Pentiphyllum flower, full-blown, found at Leppington, near Malton, and at Bugthorp, at the foot of the wolds in Yorkshire (p), is not found with us.

The Afteropodium of Mr. Edward Lbwyd (q), and others (r) is frequent in clay, with the former. It is feemingly but half formed, yet perfect and beautiful in the other half, having two flattish sides with a narrow ridge, the joints falling between each other. It is constantly found of the same sigure.

<sup>(</sup>p) Ph. Tr. No. 112.

<sup>(</sup>q) Lithophilaceum Britannicum.

<sup>(</sup>r) Hill. Hist. Foss. p. 654.

All these bodies are frequent both in stone and loose on the shores of our alpine rivulets, and in marble or limestone quarries. They are also plentiful on many parts of the sea-shore, particularly among the rocks at Holy Island, where they are called by the general name of St. Cuthbert's Beads, and are fo called by Mr. Ray (s). We find them frequently immerfed in nodules of iron-ore, with fair specimens of bivalve shells, on the shore of the brook, and in the clay-bank at Simonburn; also fingle ones so filled with the ore, that they feem only thin jointed cases, crusts, or coverings to it. We fometimes find them in masses of red ironstone on the shore of the brook at Gofton, of a blood-red throughout, in vast numbers. On the sea-shore at Druridge, near Widdrington, I have found them in a red stone, of a beautiful white, with wavy red lines running through their plated substance, both entrochoi and afteria, the stellar cavities of the latter, red. I have also found the cavity of the belemnite red, with a white circle, on a grey ground, in a red stone on the shore of the brook below Simonburn-castle. They are found both in stone and clay in fuch innumerable quantities, and with fuch numerous diflocations and bruises, in company with other marine bodies, that it is both entertaining and aftonishing to see them. Lithologists of great name differ in their opinions concerning their origin. The famous Dr. Lister (t), and Mr. Beaumont of Stoney Easton, in Somerfetshire (u), refer them to the mineral kingdom. The learned keeper of the Ashmolean Museum, Edward Lbwyd (v), and the three curious foreigners, Augustin Scilla (w), Gualtieri (x),

<sup>(</sup>s) Philosophical Letters, p. 113.

and Klein (y), refer them to the animal; reckoning them animal remains, the spines of the echinus, or appendages of the fea-flars.

The belemnite being calcined, is faid to produce the fame effects with the celebrated original phofphorus of Bologna(z).

Spar is found with us in great quantities; some white, of an irregular roundish shape, and mammillated; the mammillated of different magnitudes; others in the form of iscles, white, with purple zones; also of a light straw-colour, small at the root, swelling in the middle, and tapering to a point, with small irregular tubera, and sistulous. I have a sine specimen of the mammillated and first iscle fort, from the shore of the river Coquet, above Thropton; and two of the last iscle-species from a quarry at Bebside, by the river Blyth, both of the same length, sive inches. I have had one from the same quarry above a foot long, of the same colour, and tubulous. There are at this time many short ones under the arch of the bridge at Wark, in Tynedale, snow-white.

We have some spar with single, and some with compound crusts. I have a fine specimen of the latter fort from the shore of the brook at Simonburn; the surface thick set with irregular tubera, which being rubbed down by politure shew a beautiful wavy process, with concentric zones or circles, and in one of

<sup>(</sup>y) J. Th. Klenii Descript. Tubulorum marlnorum, 4to. cum Fig. Gedani. 1731. Per-illustri Hans Sloane, Baronetto, inscript.

<sup>(</sup>z) Du Fay's Lecture on the Phosphorus at the Meeting of the Royal Academy of Sciences at Paris, in the Year 1730.

<sup>-</sup> Account of feveral new Sorts of Phosphorus, published in the Year 1733.

them, at one corner, a figure like a shrub, of a yellowish-white.

I have a brown piece from Walker colliery, near Newcastle, with many crusts, the surface villose or nappy like velvet, glossy and shining when held up to the light.

That fort called Ofteocolla, from 65600, Os, and 1600 1600, Gluten, is often lying on the shore of the brook at Simonburn, after floods. It is so like an offeous substance, that it is often taken for the bone of some animal by those that do not know it. It is in reputation for fractures and broken bones, powdered and taken inwardly in milk, bread, an electuary, or in the common diet, till the cure is compleated; being said to expedite exsoliation, and to generate a strong and firm callus (a).

Spar is folvent by acid Menstrua.

We have Pseudo-Crystal from the lead mines at Allen-Heads of various figures and colours.

- 1. Cubic, which shews all the colours of the Rainbow.
- 2. Of the fame form, with a yellowish tinge, owing to *Lead*. We have it also *tessellated*.
- 3. Rhomboidal, of a beautiful purple, owing to Iron. We have it also with Teffella.
  - 4. Multangular, and pointed, of a sea-green, owing to Copper.
- 5. Six fided or hexogonal crystal, with large and beautiful pyramids, of a diamond lustre.

We find it also, in the same mines, in the form of incrustations, with various angular protuberances and essores, of a dazzling splendor.

Pseudo-Crystal does not effervesce with Aqua fortis. It is solvent by fire, and is used in fluxing metals.

Crystal, of an hexangular shape, is sometimes found under the gravelly surface, and in the sissures of the rocks, at Dunstonbrough-castle. It is mentioned by the learned editor of Camden, who compares it to the Bristol-stones (b). I am informed that the late Thomas Proctor, of Rock, Esq; sent some for trial on the wheel to Edinburgh, which proved not inferior to those stones for hardness and lustre. Hence they obtained the name of Dunstonbrough diamonds, but they are so rarely found, that the late Dr. Tovey, vicar of Embleton, on letting his tithes jokingly said, "That he reserved only to himself the tythe of the diamonds."

No folvent has been hitherto found for Crystal.

Small opake and pellucid cryftalline nodules are not unfrequent on our fresh water and sea strands, from which I have had the following varieties.

If. Of an oblong figure, and flattish on one side, with an admixture of a pale yellow, and a deep red, in spots and clouds. From the sea-strand near Almouth.

2dly. Of a roundish figure, grey, with an admixture of a deep red, diffused in clouds, emulating the moss-like figures in the Mocha-stone. From the shore of the brook below the bridge at Simonburn.

3dly. Of a flat shape on one side, and roundish on the other, of a bluish-grey. From the shore of North Tyne, near Park-End. These are opake.

4thly. Of an oblong, flat shape, of a pearl colour, with white reticular veins, like those we see in the leaves of some vegetables. From the shore of the brook near Nunwick.

5thly. Of an ovated shape, and of the same colour. From the shore of the Tweed. On receiving a beam of light, it refracts it most beautifully, like the Island-crystal of authors.

They are all of a smooth surface, and capable of a neat polish. They are commonly taken by inaccurate observers for sparry nodules.

Of Pebble-Crystal (c) we have some very sine, on the shores of the Coquet and Tweed; from the size of a pea, to that of a large walnut, and sometimes larger, of an unequal and irregular surface, usually roundish or flattish, pellucid as water, and capable of a high polish. I have one, from the shore of the Tweed, three inches long, two inches and a half in diameter, and about an inch and a half thick. I have others, from the same shore, of all the intermediate sizes between that and a large garden-pea. It is never found with sigured concretions.

Of the farda, or carnelian, we have the red (d), the yellow (e), and the white (f), on the same shore. We have the red from half

<sup>(</sup>c) Petridium chrystallinum, pellucidum, decolor varium. Hill. Hist. Foss. p. 563.

<sup>(</sup>d) Sarda rubescens, Id. p. 458. No. 1.

<sup>(</sup>e) Sarda flavescens. Id. p. 460. No. 2.

<sup>(</sup>f) Sarda albescens. Id. p. 461. No. 3.

the

an inch to two inches in diameter, both of an oblong, flattish, roundish, and mammillated shape, but most usually roundish, like a pebble; of a fine texture; of all the degrees of red, from a deep blood colour to that of a light florid red. We have a variety of it with veins of a pale red, and others with white veins, lighter and darker, like those of agates, disposed in irregular concentric circles, or in small and very beautiful round ones. We have also a variety of it with an admixture of a pearl-colour, the red appearing disfused in the form of clouds. It is very much used and valued with us for feals, taking a good polish, and parting easily from the wax.

We have the *yellow* carnelian from less than half an inch to near three inches in diameter, both of a flat and roundish form, like a pebble; but most commonly roundish, and of a pretty smooth surface; of an exceeding sine texture, somewhat more pellucid than the red, and capable of a high polish. We have it of all the degrees of yellow, from the pale *lemon* to a *deep* yellow; sometimes uniform throughout, but oftner with clouds of red, forming a beautiful slame-colour. We have a variety of it with veins, paler and deeper, and sometimes whitish, disposed in irregular concentric lines or circles.

We have the white carnelian, from an inch to three or four inches in diameter, both of a roundish, flattish, and oblong shape, commonly of an irregular and rough surface. It is not of a pure clear white, but a pearl-colour, white, with a tinge of blue. We have a variety of it on the shore of the Coquet, with parallel lines or veins, bluish and white, very beautiful. We have also a variety of it with an admixture of blue, diffused in spots and clouds, with irregular concentric veins, and with zones or circles, bluish and white. I found one of these in an islet in

the Tweed, called the Shingles, opposite to Norham-castle. It is of an irregular rugged shape, sive inches long, three inches in diameter, and two inches thick; very heavy. It is capable of an elegant polish. I have another of an hemispherical shape, with veins, wavy, in beautiful meanders; from the sea-shore, by Druridge, near Widdrington. It is two inches and a quarter long, and two inches in diameter; ponderous. The jewellers generally use those that are simple-coloured, and prefer them before these elegant varieties with veins. They cut out the zones or eyes, and set them in rings.

The green gem, with a flight admixture of a braffy yellow, the chryfolite of modern times, and the topaz of the antients (g), is fometimes found on the fhore of the Coquet; from which I have a fine one, of an oval fhape, a little flatted on one fide, fomewhat larger than a nutmeg, with a natural polifh; opake, and of little efteem with jewellers, though in its perfect flate of great beauty.

We have not the true chryfolite of the antients, so called from its elegant gold-yellow, the topaz of the moderns (h). The Scotch dealers in gems carry on a large trade with what they call Topazes from the Highlands, which, when put to trial on the wheel, are found only to be crystals, tinged by metalline particles. Most of the topazes used for seals and rings are of this kind.

The gem, called the Amber-Hyacinth, from its being tinged with red, and a large admixture of an amber-yellow (i), is fometimes

<sup>(</sup>g) Chrysolithus; qui topazius antiquorum. Hill. Hist. Foss. 598.

<sup>(</sup>h) Topazius; qui chrysolithus antiquorum. Id. 599.

<sup>(</sup>i) Hyacinthus. Id. p. 593.

found, but rarely, on the shore of the Coquet, above Rothbury, in the crystalliform state; from which I have a sine one, of a pebble-like sigure, with many pyramids of three quarters of an inch in length, rising from a base of purple crystal, their tops hid from the eye by an irregular sinuose crust of the same colour; their exterior sides and angles conspicuous, and semipellucid; affording a pleasing sight between two such covers at top and bottom.

Of Calculi or pebbles, of a crustated structure, capable of a fine polish, we have the following sorts; the edges of the crusts forming the elegant and beautiful figures we call veins.

- 1. A pebble with purple and white crusts; the purple of two different degrees, a lighter and deeper; some of the crusts so broken at one end, as to shew the manner of its formation. It is an inch and a half long, and an inch in diameter. From the shore of the Tweed.
- 2. A mixt red and yellow pebble, with blue, carmine, and pearl-coloured crusts; an inch and a half long, and an inch in diameter. From the shore of the *Bow-mont*, so called from its arcuated or bending course under the mountains.
- 3. A pebble with crusts of a stessh-colour, and white; the white central crust broken so as to shew the manner of its formation. From the same shore.
- 4. A pebble of a deep brown, with crusts of a light brown, white, and a pearl-colour; two inches long, and an inch and a half broad; ponderous. From the shore of the Coquet, above Rothbury.

5. A pebble with crusts of a deep amber-colour, and a bright white; an inch and a half long, and an inch and a quarter broad. From the shore of the Tweed.

There are many others on the fame shores, where the curious lithologist might meet with much entertainment after great floods. They have all exterior coats in their perfect state, like those of slints, which are very scarce with us.

There is a fine collection of Tweed-pebbles in the possession of my worthy friend, Henry: Collingwood, of Cornhill, Esq; many fine Carnelians among them. There is also a neat collection of Bow-mont-pebbles in the possession of Mrs. Selby, of Paston.

Of Agates we have the following kinds and varieties.

- r. An agate-lithoftrotion, composed of crystaline columns, the ends forming a wavy reticular work, a light yellow in the center; encircled with black; the mashes white; large, and ponderous. From the shore of North Tyne, by the islet near Chipchace-mill.
- 2. An agate-hithostrotion, composed of large astroite studes, of a button-like shape, of a corneous, slinty texture, yellow, edged with white; having much the appearance after politure of the great coralloid-lithostrotion. From the shore of the river Tyne, below Hexham.

The celebrated Dr. Hill judiciously observes, that fossil corals are sometimes so sated with crystalline matter, that they are concreted into mere agates (k).

3. An agate of a strong and deep red, variegated with a storid red, a pale blue, green, and yellow of different degrees, in beau-

<sup>(</sup>k) Hill. Hift. Fosf. p. 642.

tiful fpots; the florid red looking like drops of blood, with its ferum about it. This was found on the shore of North Tyne, by the islet near Chipchace mill. It is of an irregular shape, ponderous, and seems to be broken off a larger mass. It is the Hamachates or blood-stone of the antients (1). I have a beautiful variety of it, with an admixture of brown, and white veins, from the shore of the Tyne, near Corbridge; and another from the Coquet, above Rothbury; the florid red spots numerous and elegant. We have it also on the shores of the Tweed, and Bowmont, and the neighbouring hills. I have seen some sine ones found in those parts; cut and polished, in the possession of Mrs. Selby, of Paston.

- 4. A whitish agate, with flesh-coloured veins, spotted and variegated with a bright gold-yellow, a light and deep purple, and green. It is a beautiful species of the *Hæmachates*. From the shore of *North Tyne*, below *Chollerford*-bridge.
- red, a purple, white, and a bright gold-yellow, cast into compartments, edged with purple and a gold-yellow, in a most elegant manner; the white disfused in the form of veins; presenting to our view such a beautiful contrast of colouring, as can only be equalled by the embroidery and brocade-attire of some of the vegetable and insect-tribes. It is so excessive hard, that it was the labour of two men for two days to give it a tolerable smooth surface on a grind-stone, and to give it a politure afterwards with smiris on a lead-mold, it took me up near a week. It is a species of the hemachates. It was found in the bottom of the brook by the bridge at Simonburn, near a bank abounding with iron-stone.
- 6. An agate of a strong deep red, with large spots of a bright pea-green. It is of a fine close texture; of an irregular figure,

<sup>(1)</sup> Achates sanguineus variegatus. Id. p. 482-3. No. 2.

and feems to be broken off a larger mass; very heavy. It is also a species of the hamachates. From the shore of the brook below Simonburn castle.

- 7. An agate of a flesh-colour, with numerous spots of a beautiful red, like that of the finest carnelian; cordiform. It is the Sardicates or carnelian agate of the antients (m). It is small, and has some slight slaws, which this kind is very much subject to. From the shore of the brook at Simonburn.
- 8. An agate of a middle-red colour, variegated with spots of a bright yellow; of a flat shape. It is the *Coral*-agate of the antients (n). The variegation is always in the form of spots of a fair beautiful yellow, on a red ground, of a middle colour, between a deep and a pale red. From the shore of the river *Coquet*, above *Rothbury*.
- 9. An agate of a deep yellow, hardly to be diffinguished at a yard's distance, in its rough state, from the finer yellow wax. It is of a firm and compact texture, and capable of an elegant polish. It is the *Cerachates*, or wax-coloured agate of the antients (o). From the shore of the river *Tweed*. I have had it also from the shore of *North Tyne*. I have a large and elegant species of it from the same shore, below *Chollerford*-bridge, of a pale yellow ground, clouded with its natural colour, a strong yellow.

Grey agates, both with and without concentric veins, are found on the shores of the Tweed and Bowmont, and the neigh-

<sup>(</sup>m) Achates carneus punctatus et nebulosus: Sardachates antiquorum: Hill. Hist. Foss. p. 483. No. 3.

<sup>(</sup>n) Corallo-achates antiquorum. Id. p. 484. N. 4.

<sup>(6)</sup> Achates flavescens: Cerachates antiquorum. Id. p. 485. No. 1.

bouring hills. I have picked up fome, large and fine, by the road-fides on a rainy day, being then most easily distinguished from other stones. I have seen some cut into seals, very hand-some, in the possession of Mrs. Selby, of Paston.

We have a grey agate, with large blotches of a florid red, in great plenty in the hilly grounds on the west side of Carham, by the Tweed, many of them turned up by the spade in hedge-bottoms, and others washed down by torrents to the shore of that river. There is a variety of it streaked with red and white, refembling at a distance a piece of bacon. There is another variety mottled with white, on a grey ground. These are all subject to slaws.

Agates yield no Phosphorus...

Jaspers of an uniform structure, with no separate concretions, are not unfrequent; of which I have the following sorts.

- 1. A deep green jasper, elegantly variegated with a gold-yellow (p). It is of a roundish shape on one side, and slattish on the other; of a firm and compact texture, and a polite surface, three inches in diameter. It is a most beautiful stone. From the shore of North Tyne, by the Strother-house, below Chipchace-mill.
- 2. A jasper of a pea-green colour, variegated with a light yellow. It is of a flattish shape, and of a flinty texture.
- 3. A jafper of an olive-green colour, with dendritæ or arbufcular delineations of a bluish-black, very beautiful.
  - 4. A blue jasper, variegated with a light and deep yellow.
- (p) Jaspis durissima viridi-slavescens. Nephriticus subslava authorum. Hill. Hist. Foss. p. 578. No. 5.

- 5. A blue jasper, variegated with a yellowish-green, in beautiful streaks and blotches.
- 6. A black jasper, elegantly variegated with brown. These five from the shore of *North Tyne*, below *Chollerford*-bridge.
- 7. A black jasper, variegated with a pale yellow, with some small veins of a light blue. From the shore of Wark's burn, in Tynedale, near its offium.
- 8. A bluish-black jasper, with sless and green veins and clouds; capable of a beautiful polish. From the shore of North Tyne. I have also found it on the shore of the brook at Ovingham, near its ostium.

The bluish marbly jasper, and the black marbly jasper, both variegated with white (q), are frequent on the same shores. They are always found in loose nodules, and answer all the tests of crystal, though usually taken by inaccurate observers for fragments of marble. They strike fire with steel, do not ferment with acids, and are vitrisable.

Jaspers yield no Phosphorus.

Of Granites, formed of concretions of Quartz and mice, and answering the same tests as Jaspers, we have the following kinds and varieties; found in nodules, and loose masses, but never in strata.

<sup>(</sup>q) Jaspis marmorea, subcærulea, albo variegata.

Jaspis marmoreus, nigricans, albo variegatus. Hill. Hist. Foss. p. 590. No. 17. p. 591.

No. 18.

- r. A white granite, thinly spotted with large black spots or slakes of micæ, and some of a splendid silver-colour (r). The concretions, though large and glossy; adhere sirmly and strongly together, and form a stone of great hardness, capable of a high polish. From the shore of North Tyne. In Cornwall and Devon-shire it is called Moor-stone, where it is found in large strata, and used in the ornamental parts of buildings. It has also been worked into very beautiful tables.
- 2. A granite of a dusky ashen-white ground, with numerous, irregular, black spots; the concretions small and sine, consisting of an opake, tabulated quartz, and micæ; the latter of a deep black; both glossy; forming a beautiful variegation (s). From the shore of the brook below Simonburn-castle. An abundance of this kind of granite is said to be found in the antient temples and other buildings of Ægypt, Asia, and Italy; distinguished by modern travellers, by the name of the grey Granite. It is the Arabian granite of Dr. Woodward (t), and the Granitello of the Italians.
- 3. A granite of a red ground, of different degrees, fpotted with white, yellow, purple, and black (u); the concretions flrongly com-

Moor-stone. Woodward. Cat. G. e. 3.

Granita alba, durissima, nigro variegata; quæ incolis cornubiensium Moor-stone. Hill. Hist. Fost. 498. No. 1.

- (5) Granita albescens micis parvis nigris frequenter maculata, Italis Granitello dicta. Da Costa. Hist. Fost. p. 274. No. 3.
  - (1) Granite from Arabia. Woodw. Cat. 1. y. 6. & Cat. 1.-6. 3. Cat. A. O. d. 38.
- (u) Granita rubescens, granita orientalis rubra dicta. Da Costa. Hist. Foss. p. 276. No. 6.

compacted together, confisting of an opake and pellucid crystalline quartz, and micæ; the latter usually black. From the shore of North Tyne. This species is the Marmor Thebaicum, and Syenites, of the antients, who had it from the Upper Ægypt (w); where are vast quarries of it still to be seen (x). We have some varieties of it.

If. A dark red, fpotted with green, and black. There is a vast mass of this species lying in the river Aln, below the bridge at Alnwick. Part of it has been worked for a mill-stone by some unskilful artificers, who sinding it after much sweat to be a harder kind of stone than they were acquainted with, deserted it, with no small surprize at their mistake.

2dly. A granite of a florid red ground, with pearl-coloured or bluish-grey spots; the concretions large; no micæ in it; capable of a good polish. From the shore of the brook below Simonburn-castle.

3dly. A granite of a pale red ground, variegated with yellow and green spots. From the same shore. These are beautiful varieties.

We have also a granite of a gold-yellow ground, with grey and green spots, in an elegant variegation. This, and the other

  - (x) Ib. Ph. Lucas's Voyage au Levant. Tom. 3. p. 154, & 162.

kinds, are fometimes found with flaws or cracks, and often worn and rounded into the form of pebbles. Few of our alpine shores are without them, more or less. I have had the gold-yellow kind with grey and green spots, very elegant, from the sea-strand, near Warkworth.

The  $\mathbb{E}_{gyptians}$  were the first who built with granite. Their famous obelisks were made of it (y). The pillars in their no less famous labyrinth were also of it (z). Besides the local antient names of Syenites and  $Marmor\ Thebaicum$ , it was also called Pyropx-cilon, from its being spotted, as it were, with a fire-colour, or its red ground. Some, in Pliny's days, called it Pfaronium, from its spots and variegations (a).

Granite yields no Phosphorus.

Of *Phorphyry*, a finer kind of granite, with its fpots more neatly disposed, we have some small fragments or nodules, broken off larger masses, worn and rounded into the form of pebbles, by the currents of water.

Phorphyry, of a glowing purple ground, with angular pale red and white fpots, is very fcarce. I met with a very fmall, but beautiful fragment of it on the shore of North Tyne, below Chollerford-bridge. It takes an exquisite polish. It is the Leucostictos of the antients (b); so called from its spots and variegations.

They

<sup>(</sup>y) Trabes ex eo secere reges quodam certamine, obeliscos vocatos, solis numini sacratos. Plin. 1. 36. c. 8.

<sup>(</sup>z) Columnis reliquis e Syenite.—Id. 1. 36. c. 13.

<sup>(</sup>a) Thebaicum, quem Pyropæcilon appellavimus: aliqui Psaronium vocant. Plin. Hist. Nat. 1. 36. c. 22.

<sup>(</sup>b) Porphyrites seu lucostictos, vel, quorundam criticorum opinione, Leptopsephos Plinii. (Hist. Nat. 1. 36. c. 7.) Da Costa. Hist. Foss. p. 283. No. 1.

They had it from Upper Egypt and Ethiopia, where there are vast strata of it, as well as granite. It is remarked by Dr. Pocock, the late learned Bishop of Meath, that travellers do not rightly distinguish between these two elegant bodies. They frequently call Granite, phorphyry (c). The Egyptians had the honour of first working it, as well as granite, many centuries before the Grecian or Roman times. They made columns, flatues, and vafes of it, of fuch exquisite workmanship and elegance, as were the astonishment of the later ages; such as the Grecian and Roman artists were unwilling, though not unable, to perform. The admired Roman Kthologist, Pliny informs us, that Pollio, the Roman viceroy, under Claudius Cefar, brought statues of it to Rome, but that no body at Rome was so fond of it, as to follow his example (d). It is remarkable, that Suetonius is the only one of the Classic-authors who mentions it (e). Its excessive hardness made them neglect it, and prefer marble before it, of which they had a great variety, of wonderful beauty. All the works in porphyry, now known, were performed by Egyptian artists, by the powers of genius, and with the fame patience and unremitted industry, as the Northern nations polished their Druid beads, or magic gems, into fpheres, fpheroid, and orbicular forms.

Green phorphyry, with large angular white fpots, is more frequent. The white concretions have a flight tinge of green; fome in oblong squares, and others in the form of Entrochoi, so like

Porphyrites purpureus durissimus, maculis pallidioribus et albentibus variegatus, qui porphyrites antiquorum. Hill. Hist. Foss. p. 494. No. 1.

- (c) Description of the East, Vol. 1. p. 112.
- (d) Statuas ex eo Claudio Casari procurator ejus in urbem ex Egypto advixit Vitrasius Pollio, non admodum probata novitate. Nemo certe postea imitatus est. Hist. Nat. 1. 37. c. 7.
  - (e) L. 5. c. 50. speaking of the place of Nero's sepulture.

them as to be taken by some people for marine remains; confiling of an opake, tabulated, gloffy quartz, the Feld-Spath of the German authors, which always affects angular figures, approaching oblong fquares, cubes, and parallelopipeds, in its crystallization, both in porphyry and granite. I have a beautiful nodule of it from the shore of North Tyne, and others from the shore of the brook at Simonburn. It is capable of an elegant polish; the ground-colour of a deep grass-green. It is the Ophites of the Antients (f). They had it from the Upper Egypt, near the city of Memphis, from which they also called it Memphites (g). It had its first name from its imaginary virtues against the bites of serpents, and from the refemblance of its spots to those on the skins of fome of these reptiles. Small Tessellæ of mosaic pavements have been found of it in the ruins of Italy, but no vafes, statues, and other works of value, either Grecian or Roman. The blocks of it now found in the ruins of Egypt, are not of any great fize, from whence it is thought, that the firata of it were not confiderable for extent and depth.

Stones composed of small pebbles, and answering the tests of crystal, are sometimes found on the shore of North Tyne; from which I had the two following sorts.

If. Of a dark brown ground, thick fet with pebbles or concretions of a bright and deep red, a bluish-white, black, a pale yellow, and a yellowish-green, forming a beautiful variegation.

<sup>(</sup>f) Phorphyrites faturate viridis maculis magnis oblongo-quadratis ex viridi albentibus notatus, f. Ophites niger antiquorum. Da Costa. Hist. Foss. 287. No. 2.

<sup>(</sup>g) Plin. Hist. Nat. 1. 36. c. 7. Serpentino Antico, Italice.

2dly. Of a yellowish-white ground, thick set with concretions of different degrees of red, and a reddish-brown, from the size of a pin's head to that of a pea, in a distinct and beautiful disposition.

These curious and beautiful stones owe their colours to metalline admixtures and tinges.

## CHAP. VI.

## OF FOSSIL-SHELLS, AND OTHER ANIMAL AND VEGETABLE EXUVIÆ.

BOTH Litorales and Pelegia, or shore and ocean-shells, are not unfrequently found fossil with us. We have also some of those that are called anomalous, from their being found no where but in a fossil-state.

I shall begin with the Univalves.

- 1. The convex umbilicated Turbo (a). From a bank of blue clay above the bridge at Simonburn, where I met with two of them, one of which was fo tender that I broke it in taking out, both nearly of the same size, and cinereous.
- 2. A fmaller, of an ochreous red tinge, in a mass of iron-stone of the same colour. From the shore of the brook at Goston, near Wark, in Tynedale.
- 3. A variety of it, fmall, fmooth, and cinereous; immerfed in great numbers, and in various directions, in a fmall flone from the shore of *North Tyne*, below *Chipchace*-mill.
- (a) Testa convixa, vix persecte conica, subtus profunde umbilicata ad modum trochi telescopii. Linn. Syst. Nat. p. 760. n. 521.

Turba testa umbilicata convexa, ansractibus teretibus striatis: striis crenulasis inequalibus. Fost. Hantoniens. Pl. 1. Fig. 8.

- 4. An impression of another variety in fine yellow ochre. Found in levelling the area before *Nunwick*-hall.
- 5. A ventricose *Turbo* with a wide mouth, and an obtuse *Apex* (b); in limestone, with impressions of the bark of a resinous tree. From the shore of the brook below *Simonburn*-castle.
  - 6. A finall ventricofe Turbo, with a fharp apex (c).
- 7. A finall Turbo, with longitudinal firia, flightly immerfed in an astroite marmorite (d). These three from the clay-bank at Simonburn.
- 8. A fmall Turbo or Murex with longitudinal firia, flightly immerfed in a nodule of iron-stone (e).
- 9. The long, flender Turbo, with ventricose spires, and a small round mouth, or, the Needle-shell (f). In the same stone with No. 2, and of the same colour, an ochreous red.
- red colour. In a marmorite from the shore of the brook at Gofton.
- 11. Another, with closer and finer spires, of a bright white. In a stone found at Allen-Heads.
  - (b) Fost. Hanton. Pl. 4. Fig. 57.
  - (c) Fig. 61.
  - (d) ——— Fig. 16.
  - (e) Fig. 28.
  - (f) Fig. 49.

Turba terebra, Linn. Syst. Nat. p. 766. Bonan. Recreat. 3. Tab. 23, 24.

- 12. The Turbo with ventricose spires, called, The Trumpet-shell.

  (g). These two from the clay-bank at Simonburn.
  - 13. A fmall Trochus, with transverse strie, and a sharp Apex (h).
- 14. A cast of the larger Trochus, with an acuminated Apex. In: the same stone with the white Turbinites (terebra) No. 11.
- 15. A cast of the Trochus with an obtuse Apex. Taken out of an astroite marmorite, from the shore of the brook at Simonburn.
  - 16. The cylindric Nautilus, with longitudinal striæ (i).
- 17. A Nautilites, Lapis serpentarius, or Ammonites. Found in lime. Rone at Chipchace.

Small striated nautilite, composed of the pyrites, have been found in the coal-mines near. Newcastle, of which the late Dr. Cay had one or two (k).

The recent shell of the cylindric nautilus is supposed by Linneus to be an inhabitant of the Baltic ocean. The wreathed nautilus, or Cornu Ammonis, is a native of the Indian seas. Mariners in their voyages often observe it, who call it the Sailor, from its resembling in its motion a ship under sail. It is called Cornu Ammonis, from its having a kind of resemblance of the wreathed horns on the heads of the images of Jupiter Ammon.

<sup>(</sup>k) Ph. Tr. No. 250.

Next of the Bivalves.

1. A fingle valve of the little roundish smooth cocklea (1). In the same stone with the pale red turbinites (terebra), No. 10. and of the same colour.

Single valves of small smooth cochleæ, of a dark cinereous colour, are frequent in stone with the great stellar coralloid, and and other bodies, on the shores of our alpine brooks. There are some of them in the same stone with the white turbinites (terebra) No. 11. I have also a group of them in a stone from Allen-Heads.

- 2. The finooth wry-beaked cochlea, of the middle fize, and roundish (m). From the shore of the brook below Tecket.
- 3. A fingle valve of the longer-bodied cochlea, with longitudinal ftriæ as fine as hairs.
- 4. A fingle valve of the *cochlea* with longitudinal and transverse firix (n). Both these in a small stone from the shore of the brook below *Simonburn*-castle.
- 5. A fingle valve of the shorter-bodied cochlea, with fine longitudinal and deep transverse strice (o). In the same stone with the needle-shell, No. 9. and of the same colour.
- 6. The cochlea with eminent and depressed ridges and furrows; the middle part most elevated and extended, and the ridges most

acute (p). In the same stone with the two Trocus's from Allen-Heads.

I have it also from the clay-bank above the bridge at Simou-burn.

In the oftium of a streamlet by the Peas-meadows, below the smelting-mill at Allen-heads, there are numerous casts of it in large masses of an ochreous yellow sand-stone, with which it is almost entirely composed; said to have been drawn up the shaft of a lead-mine. I have also met with casts of it in the same kind of stone on the scar by the brook, and the road, near Simon-burn-castle, on the south-west side of the ford. I have seen fair impressions of it in the freestone from the shore of the brook below Tecket.

- 7. A flender bodied *cochlea*, elegantly marked with yellowish-brown linear spots on a white ground, and expanded valves. From the limestone-quarry at *Blake-law*, near *Simonburn*.
- 8. A fair impression in yellow other of the small ribbed pecten or scallop (q). Found in levelling the area before Nunwick-hall.
- 9. The small, fine ribbed, echinated pecten. From the claybank above the bridge at Simonburn.
- vith deep transverse furrows, and obtuse ridges, in fine yellow ochre (r). Found with the small ribbed peden, No. 8.

<sup>(</sup>q) Cardium (edule) testa antiquata sulcis xxvi obsolete imbricatis. Linn. Syst. Nat. p. 681. n. 77. Faun Suec. p. 518. n. 2141.

- 11. A fingle valve of the small tellina with deep furrows, and a crenated margin (s). From the clay-bank above the bridge at Simonburn.
- 12. The laminated tellina of a longer shape (t). From the same bank, in a bed of iron-shiver. I met with many fair specimens of it at different times, after great floods and intense frosts; the smallest an inch long.
- 13. The small laminated tellina of a more depressed shape. In the same stone with the needle-shell, No. 9, and of the same colour.

Single valves of the fea-mufcle are not unfrequent in iron-stone on the shore of the brook at Gofton. There are two of them in the last mentioned stone.

We have fingle valves of the great, round, convex Oftrea, the Oftracite of authors (u), plentifully in stone on most of the shores of our alpine brooks, and in many of the limestone-quarries. There are groups of them in large single masses of limestone in the streamlet on the east side of Simonburn-castle. They are common in limestone quarries about Stamfordham; in the large quarry at Newton on the moor, near Alnwick; in the quarry at Blakelaw, on Broad-pool-Common, near Simonburn; and in another large one on Wark-common, near Linacres, in Tynedale. In the

<sup>(</sup>s) Arca (lactea) testa subrhomboidea obsolete decussatim striata, natibus recurvis, margine crenato. Linn. Syst. Nat. p. 694. n. 143. Foss. Hant. p. 42. pl. 8. fig. 106.

<sup>(</sup>t) List. Ang. p. 19.

last mentioned quarry, some of them are of a vast size, tinged with red. Their general colour is cincreous. We never find them with double valves. Sometimes many of them include one another. Groups of them are frequent in stone with Entrochoi, and the lithostrotion, on the shore of the brook at Simonburn. These are more neat and handsome than any I have observed in quarries; parting easily from the stone with a slight stroke of a hammer. We have them in the clay-bank above the bridge at Simonburn, with other shells. There they are so tender and fragil, that it is rare to get one out intire. In the air they acquire a considerable hardness.

Two physicians, Dr. Home of Berwick upon Tweed, and Dr. Cay of Newcastle upon Tyne, used this shell very successfully in nephritic cases, and in curing such as were afflicted with the gravel. They gave it in sine powder, mixed with about a third part of Flo. Cammomel. the dose from half a dram to a dram in white wine (x).

14. A fingle valve of an Oftrea of a round convex shape, with a broad furrow down the middle from the Cardo to the extremity. From the shore of the brook at Simonburn. We have it also in limestone at Chipchace.

15. A fingle valve of an Offrea of a round convex shape, with longitudinal friæ, protuberated round the extreme margin after a fingular manner, forming a kind of frost-work. From the shore of the brook near Nunwick.

16. A fingle valve of a fmall echinated Oftrea, of a round convex shape, with a truncated beak. It has a double series of ob-

<sup>(</sup>x) Ph. Tr. No. 25.

tuse prickles towards the extreme part of the margin, and others more acute at distances on the shoulders, the beak as if cut off. From the shore of the brook at Simonburn.

- 17. A fingle valve of a finall echinated *Oftrea* of a longer fhape, with a truncated beak. The prickles are obtuse, and at irregular distances. From the bank of iron-shiver above the bridge at *Simonburn*.
- 18. A fingle valve of a very fmall, fmooth Oftrea of a round convex shape, and a truncated beak. From the same bank, where there are considerable numbers of them between the lamina of the shiver. They are of a yellowish-white, and always found of the same size and colour, free from blemishes.

These five are varieties of the great, round, convex Oftrea.

- 19. An oblong Oftrea with both valves, ftriated lengthways, with a broad furrow down the middle of the under valve. From a limestone-quarry near Nunwick. It is a variety of the common oblong species, and seems to have been bruised in its recent state.
- 20. A fingle valve of the *fmall falcated* or *booked Oftrea* (y). It is ftriated lengthways; the beak and extremity inflected, or turned inwards, forming a kind of half-round. In iron-ftone from the clay-bank above the bridge at *Simonburn*.
- 21. A fingle valve of a large falcated or booked Oftrea. It has a broad furrow down the middle, and fmall ffriæ on each fide. It

<sup>(</sup>y) Rondelet. de Pisc. Mort. Northampt. 193. tab. 3. fig. 1. Offreum minus falcatum. Lh. Lith. Brit. n. 451.

is a variety of the Concha anomia, or Conchites anomius of authors (z).

22. A fingle valve of a ventricose booked Offrea, striated lengthways. It is another variety of the same shell (a). Both these are in a fragment of limestone from the shore of the brook below Simon-burn-castle. There is a group of them; the inside of one of the latter lying upwards to view.

All these marine shells were found thirty, and some forty miles from the sea, those of our own, and those of the Mediterranean and Indian feas, found in company together, in the fame tomb. To what catastrophe could this be owing, but to the Mosaic deluge? For the testaceous inhabitants, of so many distant shores and oceans to be thus brought together, and to have the fame alpine fepulture with those of our own shores and seas, could be owing to nothing lefs; and are irrefragable testimonies against every fystem tending to support a partial or topical deluge; those fystems generally doing more honour to their authors ingenuity, than to their cause; experience being the best test, and superior to all their arguments, how artfully fo ever they are contrived, and under whatever Circaan charms they appear to delude the underflanding, to lessen the authority of a history unimpeached by Pagan antiquity; the fage Greek giving it his applause (b), and the wife Roman, though a fatyrift, doing it no difcredit (c).

- (z) Plot's Oxfordsh. tab. 4. fig. 18. Conchites anomius rugosus. List. Angl. p. 238. Gryphites latiusculus longiroster. Lh. Lith. Brit. n. 473.

(c) Quidam sortiti metuentem Sabbata Patrem, Judaicum ediscunt, et servant, ac metuunt jus, Tradidit arcano quodcunque volumine Moses.

Juv. Sat. 14.

I have not observed any fossil-remains of crustaceous and other sishes with us.

These following of land-animals have been found.

- was found about twenty-five years ago in the middle of a free-flone-rock near the iron-work at *Bebfide*, then belonging to Mr. *Thomlinfon*. It was demolished by his workmen, except one *Antler*, now in the possession of Mrs. *Fielding* of *Bebfide*-hall.
- 2. An Antler of a roe-deer. This was found three yards deep in marle at the west-boat-farm, near *Hexham*, under the mount before the house. It is in my custody.
- 3. The skeleton of an animal of an uncommon magnitude, faid in Camden to be Human, but more generally believed to be the remains of some larger kind of quadruped, facrificed at the altar of Hercules by a Syrian legion in Roman pay; turned out of the earth by the torrent of the streamlet Cor, at their station of Colcester, or Corbow, some time before the year 1695. The thigh-bone is faid to be near two yards long, the skull and teeth proportioably large, and the whole animal reckoned feven yards in length. before it was broken and disfigured by the incurious finders. The form of the skull, and other bones, which distinguish a man from other animals, undoubtedly determined the learned editor of that valuable work to call it human; otherwise from his known prudence, we may believe he never would have affirmed it, notwithstanding the opinion of the Lord Derwentwater in his fayour, who faw it. Inflances of men of a remarkable tallness often occur in history. Our British ancestry, the Cimbri, were of a gigantic stature, - immanea corpora (d).

Qui nunquam attigerant majora Cadavera corvi.

Juv. Sat. 8.

Agricola---

Grandiaque effossis mirabitur ossa sepulchris.

VIRG. Gco. 1. v. 493.

The Teutonic king, Theutobochus, fubdued by Marius, the Roman general, was fo tall, that he out-topped the trophies, the Spolia of the field, carried on the points of spears, elevated, -insigne spectaculum (e). There have been instances, well attested, of human remains being found of the extraordinary length of feventeen feet. A friend of mine, on whose veracity I can rely, saw a woman at Amsterdam, in Holland, who to her shoulders was ten feet. What difcredits the account of the Corbridge-skeleton most in the Britannia, is the opinion of the learned and curious Dr. Todd, prebendary of Carlifle, who, by the defire of Dr. Halley, took particular pains to inform him concerning it in a letter, bearing date 17th February, 1710-11. He affures us, that it might as well have been calculated at 200 or 300 yards, as feven; the ribs, shank-bones, and teeth, lying at a great distance from each other, and many of them no longer than the bones of ordinary oxen; the latter fo numerous, that a bushel of them might be gathered in an hour. He gives it as his belief, that they are the remains of oxen, or other large quadrupeds, facrificed to Hercules, laid after the Roman manner under the pavements and foundations of their fortreffes (f),

Vege-

<sup>(</sup>e) Barbararum rex ipse Theutobocus insigne spectaculum suit : qui pe de receritatis eximize super trophæa ipsa eminebat. Flor. Hist. 1. 3. c. 3.

<sup>(</sup>f) Ph. Tr. No. 330.

See Sir Hans Sloune's curious account of the Dentes exerti, the tuits, teeth, and romes of elephants, found under-ground, in his possession; and his remarks on the last he had read of

Vegetables are more frequently found fossil, than animals. Oaks of a great fize, firm and found, have been taken out of a large moss on Bewick-Moor, called King's Moss, by the road from Chillingham to Alnwick, near a noted aperture in a freestone-rock, called Catherine's cave. In another moss, on Harup-Moor, near it, there are roots of trees of an unusual fize, standing in some places very thick; some of them sound, of a beautiful colour within, like the Alder, our English mahogony. On most of our other moors, subterrene or fossil trees have been found in the mosses, some very hard, and as black as ebony. The forest of Allendale, the forest of Lowes, and the forests of Reedstale and Cheviot, all afford the like memorials.

Hazel-nuts have also been found fossil, in great quantities. Robert Hall, a labourer of Bewick, an old man, living September 3, 1760, found many in draining a moss on the estate of the late Dixy Windsor, Esq; at Wapperton, to whom he gave them, who preferved them for the inspection of the curious.

An hazel-bush, with nuts upon it, was found in sinking a coal-pit about seventeen years ago at *Lemington*, near *Newburn*, sifteen fathom deep, in a moss-earth; fair and fresh to look upon, till exposed to the air, when they mouldered away.

Impressions of vegetables, and sometimes entire fruits, and the nervous parts of leaves, are frequently found on the stonebeds of our rivers, and sea-shores, and metallic veins; the fairest

in antient and modern authors; with an accurate examination of the skeletons, and parts of skeletons, shown up and down as undeniable arguments of the existence of giants.

Ph. Tr. No. 403, 404. Dr. Thomas Molyneux's Essay concerning the bones of giants.

Ph. Tr. No. 261. Count Ferdinand de Marsigli's Dissertation in his History of the Danube, Tom. 6. upon the skeletons and bones of elephants dug up near and in the Roman Aggeres.

in iron-stone; of which I have met with some very curious, both indigenous and exotic.

- of the stalk conspicuous, also the thickness of the shell by a fracture; the conic point, or small end, in its natural colour. From Simonburn, above the bridge.
- 2. The reticular nerves, or mashes, of a leaf, found between the lamina of blue clay, several yards below the surface, at the same place.
- 3. Polypody. A fair impression of it in iron-stone. From the iron-mine at Bebside.

The late curious Dr. Jabez Cay, of Newcastle upon Tyne, had feveral fine impressions of this fern, and of the Filix storida, or Osmund Royal, from the coal-pits at Kenton, and Newbiggen, near that town. They were in the nodules of iron-stone, called Cats-beads, by our minemen; Cat-scamps, at Whitehaven, in Cumberland; Ball-mine, in Staffordshire; and Minera Ferri Pilæsormis, by Dr. Lister. Not above one in five or six have ferns in them, which lie in the middle. They split with a slight stroke at the very place, if exposed to the winter's rigour, and shew the vegetable lineaments in their utmost beauty. He had also impressions of ferns in coal-slate from Brunton and Benwell-colleries (g).

4. An American fern in relief. From Bebside-ironmine. The impression beautiful in the iron-stone (b).

(h) See Dr. Hill's Hist. of Fossils, plate 6th.

VOL. I.

Q

Another,

<sup>(</sup>g) Lapis mineræ ferri, pilæformi similis, in cujus meditullio, unum vel plura silicis solia representantur. Ph. Tr. No. 277.

Another, the leaves longer, and in somewhat bolder relief. They are frequent in this mine.

- 5. An elegant reticular impression of the bark of a pine, with the leaves in pairs in each mash; in iron-stone, from the same mine.
- 6. Another small reticular work, the mashes silled with a black shining substance, the remains of some resinous plant; in free-stone, from the sea-strand at *Hartley*.
- 7. Another, the mashes somewhat larger, in a concave nodule of freestone from the shore of the brook at Simonburn. The mashes are filled with the same kind of stone.
- 8. Another curious reticular work, in rhomboidal hollows, pretty deep, in a ferrugenous nodule from *Lee-Hall*, upon *North Tyne*. It is of the fame kind with that figured by the learned and ingenious *Da Costa*, F. R. S. in the Philosophical Transactions (i).
- 9. Another, in freeftone, the mashes large, and the rhomboidal hollows partly filled with stone, and a glossy black substance, with black wavy striæ between them. The black substance and lines seem to be the remains of a resinous bark, turned in bituminous earth to that colour. From Simonburn.
- 10. Several orders of fmall polygonal cells, roundish, inclining to oval, a fmall apex or point in the center, perforated, with undulating lines between them; in freestone, from the same place. It seems to be the impression of the bark and leaves of

<sup>(</sup>i) Ph. Tr. vol. 5. part 1. for 1757, artic. 28. p. 228.

fome refinous tree. The fagaceous Da Costa has given a figure of one like it in the Ph. Transact. before cited. The stone is of a fine shape, thin at one edge, and channelled through the middle, like the molding of a cornice.

- 11. Another, with large oval cells, and the apices oval, in the fame kind of flone, and of the fame shape, but not channelled through the middle. From the ofium of Shitlington-brook. They are very frequent, both with channels and without, on the shores of our brooks and rivers. I found one near a coal-work upon Calleley-hill, the cells deep and numerous, separated only by thin partitions. I have another from the shore of the river Coquet, above Rothbury.
- 12. An elegant reticular work with oblong hollows, evidently the impression of the bark of some tree when the sap was in it, the rugose striæ as fair as if just made. In freestone, from a quarry at Simonburn, below the school-house.
- 13. Another of the same kind, in freestone, from the shore of the brook *Hextold*, at *Hexham*; the hollows deeper, but the fine rough skin obscured by the floods.
- 14. Two pine-branches, very fair, with impressions of the bark, one of them forked; and a rhomboidal impression of the cortex, of another in relief; in freestone, from the shore of the brook below Simonburn-castle.
- 15. Another pine-branch, with part of the bark, and some of the leaves very fair, of a tawney-black colour; in freestone, from Goston; many oval cells on the exterior surface, with central apices.

- 16. A bending ear of corn, in freestone from Simonburn; externally figured like the last, but wrinkled and uneven.
- 17. A fair impression of a Bamboo, or great Indian reed, in free-stone, from the sea-shore at Hartley. I have seen one on the same shore, in company with the ingenious Edward Delaval, Esq; F. R. S. as big in diameter, as the small part of a man's arm. They are frequent in the freestone-rocks at Simonburn with impressions of the common reed.

CHAR

## CHAP. VII.

## OF ORES AND COALS.

Triftes sine SOLE Domus.

VIRG.

The hopes of treasure have incited many to travel it; some have perished in the enterprize; and others have had a golden journey; but these have generally been genius's in the favour of fortune, every way qualified for under ground adventures, by an intimate acquaintance with mineralogy, founded on experience and observation, and supported by patience and perseverance. To enumerate all my countrymen thus happily successful by those laudable talents and endowments, would take upmany pages; suffice it to say, that some of them have been founders of families of a conspicuous and exalted rank.

The antiquity of working them may be carried higher than the Romans. They were the objects of British commerce before their arrival. Casar has recorded, that there were metals in the maritime parts of the island, but he adds, not plentifully. He was too great a stranger to it to be acquainted with all its produc-

tions; he but just shewed it to the Romans. After its reduction and submission to their victorious legions under Claudian, it paid tribute in its richest and most valuable ores; particularly of lead, of which several pigs have been found in different parts with the emperors names upon them (a); and Pliny assures us, that the mines were so rich, that by an imperial edict a certain quantity was only to be worked, the veins, in the language of the minemen, appearing at the very day, whilst the mines of lead in their province of Spain were sew and poor (b). Tacitus acquaints us, that our ores, our metalla, were the lures of the Roman Eagle, and remunerated them for their toils, for their victories (c).

Our iron-mines were as well known to them as those of lead, as appears from an altar discovered at one of their walled towns, Condercum, or Benwell, inscribed to Jupiter Dolichenus, the Deity who presided over this metal, now in the curious library of Robert Shafto, Esq;

There is reason to believe, that they had also copper-works. For by their famous military way of Watling-street, near a hamlet, called Ridleys, belonging to Thomas Selby, Esq, of Bittlesden, there are conic heaps of copper-Scorie, or slag, still remaining. Some of it was lately essayed by an ingenious mineralist of my acquaintance, from which he extracted several grains of sine cop-

<sup>:(</sup>a) Stuk. Caraus. Vol. 1. p. 176.

<sup>(</sup>b) In Britannia summo Terræ Curio adeo largi, ut Lex ultra dicatur, ne plus certo modo siat. Plin. Nat. Hist. 1, 34. c. 17.

<sup>(</sup>c) Vita Agricola.

per. Stones, charged with this metal, in spots and veins, are often found on the shore of the river Coquet, and the alpine brooks of that neighbourhood.

On the west side of Kimmer-lake, near Eglingham, there has been another copper-work; the vestiges of it very fair in a hillock of slag covered over with grass, of the very same kind as that near Ridleys. On the shore of the rivulet of Bramish, and on the sides of the hills above Ingram, there are large masses of a light brown stone, charged with this metal, in slakes and spots.

The Saxons and Danes in this country were too much perplexed by wars and intestine and civil broils to have any such works. And even for some time after the conquest by the Normans, we find that mines on the northern borders were very rare. There were so sew in the reign of King Edward III. that the governor of Berwick upon Tweed, 1356, was obliged to have minemen from the forest of Dean, and the more southern parts, to assist him in retaking the town from the Scots (d). Iron-works in the preceding reign, 10 King Edward II. were so scarce, that the Scots in a prædatory expedition in that year, met with none worth their notice till they came to Furness, in Lancashire, where they seized all the manufactured iron they could find, and carried it off with eager joy, though so heavy a carriage, and preferred it to all other plunder (e).

The Romans were as well acquainted with our pit-coal, as with our ores and metals. In digging up fome of the foundations of their walled city, Magna, or Caervorron, 1762, coal-cinders, fome

<sup>(</sup>d) Hol. Chron. Vol. 11. p. 386.

<sup>(</sup>e) Id. p. 323.

very large, were turned up, glowed in the fire like other cinders, and not to be known from them when taken out.

The principal lead-works with us are at

Allen-Head,

Shilden,

Coal-Clugh,

Fallowfield.

Allen-Head-mines have been worked for time immemorial. The ore lies in the form of a tree, recumbent. The method of our miners working them, is by finking a fhaft till they come to a vein, and then they make crofs-cuts, and with eager purfuit follow the feveral branches, or ftrings, as they call them. They had formerly another method, still practifed about a mile to the fouth-east from these, near Rokehope, within the liberties of the bishoprick of Durham. This was by flooding, or hushing, as they phraze it; making a large bason or reservoir of water, which being let out by a fluice in a full stream through a cut or opening from a descent, with an irresistible impetuosity sweeps away, on frequent repetitions, all the various substances which compose the roof of the mine, freestone, iron-stone, whin-stone, lime-stone, spar, and tale, and, at length, the ore itself, with gravel, stand, and other extraneous matter, in gentler currents.

Coal-Clugh-Mine is three miles to the fouth-west from Allen-Head, near the source of the rivulet of West-Allen; by a clugh, or boggy hollow, as the name imports, black and hideous to look upon. It is said to be the deepest lead-mine in England, 100 sathom, a subterraneous waggon-way, of a mile in length, leading to its Ostium.

The lead-mine at Shilden was very rich till of late years. It now gives employment to feveral hands, and has two fubterrene engines to carry off the water.

The lead-mine at Fallowfield was exceedingly rich for many years, till it was drowned. It is called by the miners, the old man, who always mention its internal wealth with rapture. It was lately opened, and a fire-engine erected. It gives employment to about eighty men.

There is a lead-mine now working near *Shilden*, reputed rich in ore, discovered by a meer accident, by a countryman's stumbling upon a piece of ore lying at the very day.

There are other veins of ore in that neighbourhood, but not of confequence enough to be particularly mentioned.

There was formerly a lead-mine in Rothbury-forest, the ore in fmall lumps, enclosed in a white talcy stone.

There was also another on the brow of a hill by the brook above *Stonecroft*, near *Satling stones*; the ore in the same kind of stone, of which I have gathered several specimens, both on the shore and in the bottom of the rivulet.

Another was opened fome years ago at Sharply, near Simonburn, by Sir Lancelot Allgood, of Nunwick, Knt. the ore good, but not in fufficient quantities to continue working it.

A string, or small vein, was lately discovered in the middle of the villa of Little Houghton; the ore lodged in coarse spar, tale, and ordinary marcasite, found near the day; in good esteem, Vol. I.

and worked by the owner, Mr. Henry Penreth, merchant in New-castle, for some time, but discontinued after a few trials.

There was lately a boring for lead-ore at Overton, near Simon-burn on the effate of Sir Ralph Milbank, of Hannaby, Bart. but it was found not to answer the expence of working. I have two specimens of the ore, one of them a small nodule, very ponderous, of that kind which our miners call, Float-Ore.

Northumberland-lead-ore yields a moderate share of silver, is soft, ductile, and fuses kindly in the sire. The ingenious Dr. Woodward informs us, that there is a lead-ore got at \_\_\_\_\_\_ brought to Newcastle to be worked, which yields betwixt twenty or thirty ounces of silver per ton, which is the richest he knew of in England (f). The great Mr. Boyle acquaints us he has known it observed, that lead-ore, which is poor in its own metal, affords more silver than others; and assures us, that he had some lead-ore, which on trial yielded three parts in four of good lead, and yet in the cuppel scarce yielded an atom of silver (g).

From the lead-mines at *Allen-Heads* and *Fallowfield*, I have been furnished with some lead-ores, curious and beautiful, deserving notice.

- 1. Tessellated lead-ore, ponderous and rich, the tessels mostly of a parallelopiped figure, and of a fine natural polish.
- 2. Globose, multangular lead-ore, with plain sides, in the manner of crystalline spar, but not regular; called by the

<sup>(</sup>f) Cat. of Fossils, Part 2d. p. 84.

<sup>(</sup>g) Ph. Tr. No. 19. p. 339.

miners, Diced Ore. I have another specimen, broken, exhibiting a beautiful natural politure.

- 3. Diced ore rifing in feveral orders from a plate of the common ore.
- 4. Half lead-ore, and half crystalline spar, of a parallelopiped figure.
- 5. Tuberous, cavernose lead-ore, with many short arborescent columns, of unequal lengths, some on a plane, and others on the sides and steeps, glossy and sparkling. These five from Allen-Heads.
- 6. Lead-ore of various colours, like those of the Iris, or rainbow, called by the miners, Peacock's-tail Ore, from its refembling the colours in the train of that beautiful bird, red, purple, blue, green, and yellow; the last colour owing to its own metal, the blue and green to copper, the red and purple to iron. This ore may be preferved in all its beauty under a cover, not exposed to the air. Without that caution, it gradually lofes its admired tincts. It is broad-grained, fuses badly in the fire, and yields not fo much lead as ore of the same texture of an uniform colour. The flores of the common ores in fusion frequently exhibit the fame colours, and are preferved fometimes by the refiners for prefents to the curious. They call them the Skimmings of leadore. An ingenious gentlewoman from the fouth, lately here. on having some presented to her, diverted herself in making them into flower-works of various kinds; of which I have some in frames under glasses, beautiful imitations of nature, some of carnations, and others of tulips and ranunculus's, both in little R 2 baskets.

baskets, and without, of the same materials. The colours are splendid and permanent.

- 7. Snow-white, arborescent lead-ore, like some of the submarine corallines.
- 8. Another piece, the branches fewer and shorter, and more irregular, the intervals a beautiful frost-work.
- 9. A cylindric column of white lead-ore, tubulous, three inches long, and two inches in diameter, the furface thick fet with arborescent shoots, of unequal lengths.
- no. White lead-ore composed of several transparent tubes, of unequal lengths, the longest two inches and a half, and bild at the end, in the base three inches over, at the extremity two inches; a small cylindric column, an inch long, affixed by the ends on one side, making a cavernula or hollow underneath, towards the middle, the surface sparkling with pointed studes; the rest, towards the base, also glossy with ramose efflorescences.
- 11. A column of white lead-ore, tubulous, compressed, and tapering, with a ramose shoot at the extremity, and a longitudinal furrow down the middle on one side; oblique transverse striæ on the other side; the surface glossy with short pointed shoots.
- 12. White lead-ore, with a vein of blue lead-ore running through it, very bright, with a concretion of the fame at one end, angular and pointed, like crystalline sparks, the blue emulating the lapis lazuli in lustre.

These seven, the party-coloured, and white sigured ores, are from the mine at Fallowsield. The tubulous arborescent kinds, have the appearance of stillactitious crystallizations. They are the easiest in susion of all the lead-ores.

The only iron-work of any eminence with us at prefent, is at *Bebfide*, on the fouth fide of the river *Blyth*, about four miles from the fea-port of that name. The ore is digged out of the hanging banks by the river with great labour and pains, of various colours, and of various degrees of texture and hardness, some as foft as common clay till hardened by the air. The heaviest and richest in metal is mostly of a liver-colour, or a deep brown.

There was fome years ago an iron-work at Lee-Hall, on the edge of the river of North Tyne, near Bellingham. The ore is plentiful in the strata of a romantic precipice on the east side of the river; both the liver-coloured crustaceous, and clay-kinds; the first ponderous and rich in metal, some of it of equal weight with malleable iron that has passed the fire. It was under the direction and conduct of Mr. Wood, fon of Mr. Wood, famous for being the projector of the halfpence and farthings for Ireland by patent. He made a good deal of bar-iron, but charcoal becoming scarce, he removed to Lancashire, where he attempted to make it with pit-coal. This has been attempted by others, but not with that happy fuccess one could wish for. The ingenious mineralists of Colebrook-Dale, in Shropshire, have the art, from iron-ore and coal, both got in the fame dale, to make iron brittle or tough at pleasure. They cast cannon so fost, as to bear turning, like wrought iron.

The famous Mr. Boyl observes, that about three tons of ironflone in some iron-mines will yield one ton of metal. And on the authority of Mathefius he informs us, that a little gold is not unfrequently found in iron-ore (h).

We have fome iron-stone and ore of a peculiar structure, figure, and colour, deserving notice.

- 1. A ponderous mass, seven inches long, and thirteen inches over, in the thickest part, grey, with sibrous septa of black talc, villose and nappy, like velvet. From the shore of North Tyne, below Chipchace-mill.
- 2. Of the shape and size of a carpenter's hand-plane, ponderous. From the shore of the brook below Simonburn-castle.
- 3. Very much refembling a *Bonum Magnum*-plumb, with a fliort flem or pedicle; one fide fmooth, the other tuberculofe and granulated, irregularly, but very neat. From the fhore of the brook at *Simonburn*.
- 5. Resembling half of a nectarine split in two, of a sine grain or texture, a faint red, with a *Neucleus*, covered with a thin silm or skin, tinged with yellow. From the same shore.
- 5. Like the head of a finall iron-bolt, broken off, with an enamel of a copper-colour.

Of the manner of making iron, see Musico de Fisica & de Experienze, &c. by Signior Boccone.

<sup>(</sup>h) Ph. Tr. No. 19.

- 6. Of a digitated figure, an inch and three quarters long, two inches and an half over at the base, and two inches over at the extremity; composed of cups or crusts including one another.
- 7. Another, fmaller, an inch and three quarters long. Both these have a thin film or enamel, of a yellow and brown colour, the extremities rounded, obliquely.
- 8. Another, fomewhat curvated, rounded and fwelling in the middle by a thick arborescent *Coxtex*, the cup at the small end fallen off, and preserved for view.
- 9. Another, an inch and a half in length, two inches and a quarter over at the base, and two inches at the extremity, the brims of the cups projecting, forming the sigure of a screw, the ridges or eminences equidistant, with a cuticula somewhat rough, and where rubbed, appears as if gilt by the golden *Pyrites* or marcasite.
- at the base, and an inch over at the extremity, the edges of the cups a little raised, and conspicuous under a thin film, exhibiting a slight view of its consiguration and structure. These six from strata of iron-stone on the north side of the brook at Simonburn, above the bridge.

There are fome others with vegetable delineations, mentioned in another place.

We have at prefent no Copper-works. From the feveral marcafites and pyritæ found in the coal-mines at Pleffey, Newbiggen, and other coal-works, large quantities of vitriol or copperas, as it is called called by the artificers, are made at Hartley, and at Dent's Hole, near Newcastle. The pyritæ are found in strata, in small nodules; the marcafites in perpendicular fiffures. They both hold copper, but in fo fmall a proportion that it is not worth Sulphur and arfenic is frequently extracted from The pyrites is fometimes found folid and unmixed with extraneous matter, both in our lead and coal-works, but chiefly in the former; of various figures, in irregular clufters; orbicular, or in large balls; also tabulated, in regular cubes. I have feen large masses of the first fort from the lead-mines at Allen-Hands, and of the latter I have a small specimen from the coal-work at Chirton, in the form of cubic pseudo-crystal; two cubes joined together, one of them unfortunately mutilated by a fracture, of a pale yellow colour, glaring and shining like polished steel.

Our coal-works are numerous. The principal, for export, are those at

Pleffey, Killingworth-moor,

Hartley, Newbiggen,

Tynemouth-moor, Wylam, Chirton, Byker, Long Benton, Walker.

These mines are of various depths. The deepest and of the greatest curiosity is that at

Walker, by the river Tyne. It is 100 fathom. The feam of coal is 8 feet, and 5 inches and a half, thick. There are two ventilators worked with a machine by the help of the fire-engine. This machine is also applied to turn a wheel for raising coals, bring-

ing up a corve of 20 pecks, 100 fathom, in the space of a minute, the horses moving in a walk (k). Half of this mine belongs to William Ord, of Fenham, and the other half to Joseph Reay, and William Penreth of Newcastle, Esqrs; held by lease from the corporation of Newcastle.

The Long Benton-mines have been in high reputation for feveral years, but are now faid to be going off. One of them is on the fouth fide of the village. It is called the bason. It is in depth 72 fathom. The main seam is in thickness about 7 feet. There is another on the west side of the village. It is called, The Delight. It is in depth 74 fathom, and 1 yard. The main seam is 7 feet thick.

Killingworth-moor-mine, called also New Benton, was lately opened by the proprietors of those of Long Benton. It is in depth 70 fathom. The main seam is near 7 feet thick; the several strata of earths and minerals observed in it for 36 fathom, are as follow; 1st. clay, 2dly. a brown gravel; 3dly. a soft pale blue stone; 4thly. a white post, or a very hard chalk-like stone; 5thly. a soft green stone; 6thly. a hard blue stone; 7thly. a white post mixed with whin; 8thly. of metal, or black slaty stone, 4 feet; 9thly. coal, 8 inches thick; 10thly. metal, 6 inches; 11thly. coal, 16 inches. I had this account from the miners on the spot.

Byker-mine, in Sir Harry Lawfon's liberty, is 70 fathom, and 1 yard in depth. The main feam is 5 feet, 10 inches thick. Within two feet of the roof is a band or load of stone which reduces the coal-feam to 5 feet, 9 inches. It is called, the high main coal-

<sup>(</sup>i) See the description and drawing of such a machine, &c. by Keen Fitegerald, Esq; in the Philosoph. Transact. Part 2. for the year 1758, p. 727.

feam. The chief strata of earths and minerals observed in this mine, are blue metal; white post, 6 fathom; a slaty stone, 5 yards; and next to the coal, an hard white stone-post, 10 fathom, and 1 yard. Seams of coal, of various thickness, lie variously between the strata, not workable. There is another mine hard by, of the same quality with this. There is a dyke in it, called Thistle-pit-dyke, lying north-west and south-east. It is believed to keep a very true course. Many small dykes branch from it, resembling the root of a tree, in different directions.

I have had a fight of the boring-notes of some of the other mines, but they are not suffered to come under the public view, being kept as *Arcana* by the proprietors.

By the best observations of the mine-men, the coal-seams generally rise to the north-west, and dip to the south-east.

There are two forts of vapour terrible to men concerned in coal-mines; one fulminating, and the other arfenical; the first volatile and active, making the candles burn precipitately, taking fire, and giving an explosion like the blowing up of a citadel with gun-powder, destroying the men, and ruining the works; the other gross and foul, not suffering the candles to burn, in an instant extinguishing both them and the human lamp, killing by its poisonous nature. On the 4th of June, 1761, two overmen, father and son, of the name of Joblin, were both killed by the first in one of the mines at Byker, and remain there. In the same year, a young man was suffocated by the latter on entering Newbiggen-mine, but recovered by being laid on his belly, with his mouth in a fresh hole made in the earth, the usual remedy on such occasions. Against this fort of vapour or damp, as it is called, a large iron-lamp, sull of coals, is kept continually burn-

ing in the mine; and to guard against both kinds, a free currency of air is circulated through all the works, entering one, and coming up another.

Two expedients have been tried by the late ingenious Mr. Cavliste Spedding, of Whitehaven, for the safety of the workmen in coal mines, infested with the fulminating vapour; one is by framing the perpendicular shafts or pits with timber where it is fuspected to be, and to place a tube of about two inches square in a small hollow behind it, elevated four yards above the Offium of the mine, to collect the damp air to one fide of it, and to convey it out of its precincts; the other is by the use of steel and flints fixed in a fmall engine with a wheel, which give a glimmering light to the miners; this fort of vapour not firing by fparks, though it does by flame. When it comes out of the top of the tube it is cold as frosty air, yet after it has been imprisoned and confined in a bladder even for near a month, it will take fire at a lighted taper or candle, if gently pressed into it through the orifice of a pipe, and when the candle is withdrawn, will continue burning till it is all fpent.

In the grounds at *Benwell*, about a quarter of a mile north from the river *Tyne*, a coal-mine took fire at a workman's candle, negligently placed, and continued burning about 30 years, though at first so small, that a proposal was made to put it out for so low a reward as, 2 s. 6 d. but it was not accepted. It afterwards acquired such force and strength from the kindled sulphurs and bitumens, that it raged with fury, in various directions and depths; sometimes taking its course east and west, and at last to the north, into the grounds of *Fenham*, near a mile from its first appearance, committing great ravages in its way, only conspicuous by its slames and columns of smoak in the night.

The eruptions at Fenham were in near twenty places. I have not heard that it cast forth stones of any considerable magnitude. Flowers of sulphur, mixed with fal ammoniac, were found concreted on pieces of alum-stone, slate, and the neighbouring furz, of which a physician of Newcastle upon Tyne, Dr. Hodgson, gave an account to the Royal Society (1), who could discover neither common falt or nitre in the soil or springs about it, the coalwater being all vitrioline, and tinging red with galls, and other neighbouring sountains being destitute of mineral salts. But he observed, that the coal-ways were mended with a fort of slate, composed of coal, alum-stone, and marcasite, cast in heaps and burnt, from which he had often collected both brimstone and sal ammoniac.

Some of the falt ejected by this bitumenous vulcano was, upwards of fix inches broad. It was first observed and gathered by Dr. Richard Gilpin, in whose company Dr. Hodgson proved it by an experiment to be fal ammoniac. For colour, some of it was grey, some snow-white, freed from the black fator of the coal by the intense heat of the fire.

Factitious, fulphurous air collected from the folution of metal at the time of their effervescence, especially iron, 3ij of filings being mixed with 3ij of oil of vitriol, and 3viij of common water, will exhibit the same phænomenon on trial after the same manner as the fulminating damp, and if the slame of the candle is suffered to enter the neck of the bladder, the inclosed air will take sire, and go off like a gun with a great explosion.

Dr. Brownrigg, an eminent physician at Whitehaven, drew up a history of damps, which was communicated to the Royal So-

ciety by the late learned and reverend Dr. Hales, but dropt his defign of finishing it, to the regret of those who are acquainted with his great abilities. He has observed, that the fire-engine seems not yet to have attained to its greatest degree of perfection. He thinks there is reason to hope, that either by increasing the steam, or by augmenting the force, it may be brought to work with much fmaller boilers, and with a very moderate expence of fuel; and under fuch circumstances it may be applied to a vast variety of purposes, and become of much greater use to mankind (1). His late friend, Mr. Carlifle Spedding, before-mentioned, an excellent mechanic, was fuperintendent of five at Whitebaven, to which he made many confiderable improvements. The fame has been done by Mr. William Brown, of Throckley, in this county, particularly in the engine erected for the coal-mine at Walker, already noticed, in great reputation for his skill in mechanics, and his fagacity and prudence in the direction and management of coal-mines.

Those round Newcastle were ordered to be fired, 19th King Charles I. 1643, by the Marquis of Newcastle, General of the King's forces, then in the town, besieged by the Scots, whose General, Lesley, preserved them by surprizing the boats and vessels (m)...

They had also a narrow escape from being fired by the Scots after their defection from the parliament, 1648, under their Leader, Monroe, who, on the news of a party of his countrymen rising against him, under the conduct of the Marquis of Argyle, spirited up by their ministers, ordered his troops homewards,

<sup>(1)</sup> Ph. Tr. Vol. 49. Part 2d. for 1756.

<sup>(</sup>m) Whitlock's Memorials, p. 78.

the nearest way over the Tweed, in such haste, says Whitlock, that they had almost left their plunder behind them, had they not preferred it to life (n).

Coals of curiofity for their hardness, colour, and sigure, obferved in our mines, are as follow.

- 1. A hard, gloffy coal, in large masses, preferable to all others for strength and duration. It is usually called *Splint* by the miners. From the mine, called The Delight, at *Long Benton*. There is some of this coal in the mine at *Wylam*, belonging to *John Blacket*, Esq;
- 2. Coal with a thick enamel of filvery marcafite. From the mines at Plessey, belonging to Matthew Ridley, Esq;
- 3. Coal glowing with all the colours of the rainbow in the most beautiful enamel, much exceeding those observed in lead-ore, and more permanent, if preserved with the same care, under a cover, dry, and from dust. From Chirton-mine, and from one at Inghow, near Stamfordham. That from Inghow has the finest tincts, most splendid and rich, as if raised in parts, and in a kind of relief. Some of it has a high natural polish, like a mirror. Some of the common coal in this mine is a glossy black, of a fine politure, and breaks into rhomboid and parallellapid figures.
- 4. The Ampelites, or canal-coal, very fine. From the mines at Long Benton, and Walker, but in no great quantities. That from Walker very much refembles the inflammable fosfil, gagates, or jet. Snuff-boxes, and other toys, are frequently made of this kind by ingenious artists.

## CHAP. VIII.

## OF TREES AND PLANTS.

IN the British, Roman, and Saxon times, Northumberland abounded with forests and groves of oak, and other timber; many villas taking their names from their woody fituation; as Woodrington, i. e. a town in a wood, encompassed with it, as in a ring; Woden, i. e. the extremity or end of the wood; Dru-ridge, i. e. a grove of oaks; the oak being called Dru by the Britons, from its being a facred tree, their priefts or Druids performing their idolatrous rites under its shade. The ocean, as if offended with their impiety, has fwept away their grove at Druridge, the stumps and roots frequently visible in the mud after the retreat of the tides, large and numerous, and fometimes branches and trunks by their fides. Cheviot is upon record for its oaks and brushwood, in such abundance, that it was called the Great Wood of Cheviot, by way of eminence (a). In the reign of King Egfrid, the Christian Saxon, Hexham was furrounded with thick woods (b). In the reign of K. Henry VIII, Cheviot was in a manner disrobed of its beautiful verdure; shrubs, and some crooked old trees being only to be feen. Glen-dale was much in the fame flate; as were Reed's-dale; the vale of South Tyne, from Hexham to Tynemouth; the country between Newcastle and Morpeth, and Bam-

<sup>(</sup>a) Lel. Itin. Vol. 7. p. 63.

<sup>(</sup>b) Prior Richard. Inter x scripto: es

broughshire. Between Morpeth and Alnwick there was a fine shew of wood, and many parks; but little between Alnwick and Ber-wick (c).

Under the authority and countenance of the legislature in the reign of K. Edward VI. upon the division and enclosure of property, our woods increased, and their owners began to think them worthy of their care and cultivation; all the vale-soils, and many declivities and hills, being naturally inclined to wood. The houses built fince that period, shew its plenty, particularly of oak; the planks thick and broad; the beams of a surprizing length and magnitude, two often lying near one another, where one might serve; strength and security being then preferred to order, and the beauty of design.

The yew was a favourite tree with our ancestors in the days of archery, some of which are still remaining, of a great size; the largest in the church-yard at Beltingham. In the cliffs, on the western margin of the Allen, they grow naturally, their roots and sibres receiving their nourishment from such light earth as they find between the crevices and broken strata of the rocks; their verdure beautiful by the passing stream.

Hollies feem also to be as natural to our alpine soils, on the banks of rivers. The largest and handsomest I have observed, are on the east-side of West Allen, at Monk, opposite to Whitsield-hall.

Silver-firs grow to an extraordinary fize near the hills of Cheviot. Before the west front of Brandon-White House, there are two very large; one of them judged fit to be a mast for a 20 gun ship;

<sup>(</sup>c) Lel. Itin. Vol. 7. p. 63.

being at the root about feven feet in circumference. A great encouragement this to replant the neighbouring hills and mountains, whose shade and verdure would be one of the greatest beauties of our country, and the timber a fund of wealth!

The *larix*, or *larch-tree*, is one of the most ornamental and valuable trees of our groves and plantations; its form graceful, its timber known from experience to exceed any tree for duration under falt-water, except the cypress (d.)

The Cypress, the Cedar of Libanus, the Weymouth-Pine, the Balm of Gilead-Fir, the Spanish chesnut, and the Walnut-tree, thrive very well in the warmer and better foils; fome of them near the fea. In the garden of Ralph William Grey, of Backworth, Efg; there is a Cypress about twenty feet in height; also a Spanish chesnut and a walnut-tree standing together, fit for timber; the latter bearing nuts, and the cypress full of cones, 21st August, 1762. There are two walnut-trees at Ashington, the seat of George Sandiford Crow, Esq; of a remarkable fize; one fix feet, nine inches in the girth, the trunk to four leading branches, nine feet, four inches and a half; the other fix feet in the girth, the trunk to two leading branches, fix feet four inches and a half. The nuts both here, and at Backworth, arrive at no higher perfection than to ferve for pickles. This tree does not lose its leading shoots at either place, as it does in the vale of North Tyne; which is owing partly to mifmanagement, and partly to the foil; the gardeners usually cutting off the tap-roots, and the foil frequently upon an ochreous iron-shiver; both which hinder their thriving, bring on an atrophy and decay; the bark turning fcabrous, and the trunk deformed with blotches and fcars. In a grove at Fenham, the feat

<sup>(</sup>d) Wiston's Naval Architecture, fol. Amst. 1671.

of William Ord, Efq; the other refinous trees make a fine shew; their bark florid, and their shoots vigorous.

The Beech and English Elm are cultivated with great fuccess, both for their shade and timber. The former was facred in the times of Paganism among the northern nations, on which they wrote their laws (e).

The Scotch Elm grows to a great fize; its natural fituation by the fides of brooks and rivers, and even in the clefts and precipices, and fometimes on bleak and barren hills, with the ash, being its rival in combating winds and tempests.

The more valuable fruit-trees, as the *Peech*, the *Apricot*, the *Nectarine*, and the *Vine*, have of late been favoured with firewalls, to forward their vegetation, and to give their fruit that mellowness and flavour, which our northern Sun denies them. In some of the warmer vales they succeed pretty well without that aid, but in most other places they demand it. It must be confessed, that fruit from the fire-walls is preferable to all others, and will admit of no competition, either for taste or beauty; particularly the grape; however assisted by situation, exposure, walls, and glasses.

The White-Heart Cherry is a shy bearer on most of our walls; the other kinds, the Black Heart, the May-Duke, &c. bear in great perfection; the Morel, against a north wall, excellent.

No culture has yet been found capable to give the golden Pippen its true flavour in this climate, except it is treated like the vine, &c. planted against a fire-wall. The other orchard-trees, both

<sup>(</sup>e) Ola Rudbeek. Atlanticæ. Pars 3. Fol. 1698.

apples, pears, and plumbs, do, for the most part, extremely well, under proper management and culture, neither defective in flavour nor size; not disdaining to be planted even near the sea, if well sheltered.

Few counties produce a better flore of wild plants. I shall only take notice of such as are most remarkable for their beauty, or for their medical and occonomical uses.

1. The Bird-Cherry (f). In woods, by waters, plentifully. The flowers are white, in large pendulous clusters, of an ageecable fcent; the fruit black, round at first, and afterwards of a cordated figure. Upon very old, tall trees, I have seen the fruit as large as those of the garden black currant. It is of an agreeable taste in its full ripeness, but the birds seldom let it continue on the tree till it is in that state, commonly feeding upon it on its first changing from red to black. The alpine common people are very fond of it.

The Mountain-Ash, or the Quicken-Tree (g). In woods, and about rocks, by waters. The fruit is of a beautiful yellowish-red, in pen-

pendulous clusters. It was a facred tree with the *Pagans* of the northern nations, who wrote their laws upon its wood, as well as upon the beech \*.

- 3. The Elder-Tree (h). In hedges. About Newbrough, the two Wardens, the Hermitage, and Hexham, plentifully. The interior bark has been long in reputation for curing burns and fealds; the fpring-shoots for a table-pickle; the flowers for a cordial by infusion and distillation; the fruit for making an excellent wine.
- 4. Marsh-Elder (i). In moist woods, plentifully. The flowers are white, in large umbels, succeeded by red fruit, glossy and beautiful.

These four trees do not flower with us till the beginning of June. The fruits are ripe in the latter end of autumn.

- 5. Dwarf-Elder, Walwort, or Danewort (k). On the west side of the church-yard-wall at Chatton, by the river Till. At Purloy-Green, near Shitlington-hall, in Tynedale, plentifully. In a farm-yard at Tecket, sparingly. It slowers in June. The slowers are white, in large umbels; the fruit black. It is diuretic and aperient, used in obstructions of the Viscera, dropsies, and jaundices. For inflammations, scalds, burns, and the venomous bite of any animal, it has been used with eminent success. It is said also to assuage the pain of the gout. It has an agreeable smell in an ointment †.
- 6. The Euonymus (1). At the west end of the rectory-wood at Simonburn. At Capons-clugh, near Allerwash; also in the Bush-wood, on the banks of South Tyne, near the same place. The older shoots are four-cornered; the corners or angles brown; the flat sides of a pea-green. The younger shoots are all green, resembling jessamy. The slowers are at the extremity of the branches, of a yellowish-white. The fruit is angular, of a purplish-red, with an ovated seed of a bright orange-yellow. It slowers with us in

Helv. p. 423.

June. The fruit is ripe in the latter end of autumn, and does not fall off till towards Christmas. It is the most beautiful of all our winter flowering-shrubs. It is not common.

The black berry-bearing Alder (m), with white flowers at the Alæ of the leaves, faid to grow in Thorny-holme, in Whinfield-park, in Westmorland\*, and plentifully in the moist woods and hedges in some of the southern counties, especially about London, does not grow with us where I have been.

- 7. Upright Juniper (n). Among the bushes and trees on the banks of the Tyne near Ryding, below Hexham. It is sometimes removed into the garden-shrubberies. It grows to no great height with us.
- 8. Procumbent alpine Juniper (o). On barren heaths. On Broad-pool-Common, near Simonburn. It is confamily loaden with fruit, but little regarded with us. In the highlands of Scotland, over against

the isle of *Skie*, and in the *Skie-isle*, the natives are faid to bathe their children in the infusion of the wood, when the small poxis epidemical, and those who neglect this precaution are observed to die, of which there are several instances \*.

- 9. The Sweet Briar or Eglantine (p). On the edge of the military road by the 12th mile-stone, on the west-side, about forty yards from it. There is a very large bush of it, grateful by its scent to the passenger. I have also observed it growing sparingly on the bank on the north side of the Coquet, at Warkworth, almost opposite to the church.
- 10. The Framboise, Hindberry, or Raspberry (q). About hedges, and in woods, in stony places, plentifully. On the north side of the brook below Tecket, among the moist rocks, it bears as large fruit as any I have seen in gardens, the branches hanging over the rocks, and down to the ground, with their weight; of a most grateful taste, far superior to those that are under culture, and nourished with dungs.
- 11. Double white-flowered Dewberry-Bush (r). In a stony place near the foot of the bank in Tecket-wood, by the path leading

westward from the rectory-den, at Simonburn, to the brook, plentifully. The flowers are large, of a bright white, in a double feries. It constantly produces the same flowers, both in its wild | state, and under culture. It is a variety of the common Dewberry (s). It flowers at the same time, in the latter end of May.

- 12. The herbaceous Stone-Bramble (t). Amongst the gravel at the bottom of a high bank about two-hundred yards below the remains of a mill at West Dibden, called Whinetly-mill, in Hexhamshire. The children of the neighbourhood, who gather the berries to eat, call them wild Cherries. They are of a beautiful red. It is a scarce plant.
- 13. The Cloud-berry, Knot-berry, or Knout-berry (u). On Cheviot, plentifully. The fruit is red, of an infipid taste. It is accounted a good antiscorbutic.

In the bottom of the wood at the Oftim of Gofton-burn, on the north fide. On the strand of the brook at Slaterfield, by the path to Simonburn. The fruit is conic, of the fize of a small nutmeg, finer tasted than the garden-kinds. It loves a water-sand and gravel, and a low shady situation. It is a variety of the small, rough, shining-leaved, common strawberry of the woods.

The fmall white Strawberry (x), does not grow with us, but as it may have escaped out of gardens. It grows plentifully on the tops of the brick-garden-walls at the Half-way house between Newcastle and Tynemouth, with no other nourishment than what it receives from the mortar, of lime and sand, between the bricks; of a much finer flavour than when it grows under culture on the ground below.

- alpine rocks, and upon heaths. On Calleley-hill, plentifully; where the fruit is the largest of any I have seen, of the size of the garden-black current.
- 16. Thyme-leaved, Marsh-Wortle-berry, or Crane-berry (z). On small hillocks among the Sphagnum in mountainous mosses. On both sides

parameters and be beginned to the dealer of the

fides of the Roman wall, in the mosses, westward; in great abundance in wet summers. The flower is of a beautiful scarlet, consisting of four long segments, revolute, with eight stamina. The fruit is ripe in autumn, of a florid red, spotted with a deep purple, and on its going off entirely of a deep purple. It is used for tarts, for which it is much valued; of a most grateful taste, cooling and refrigerant.

- 17. We have the fmall deciduous-leaved black Wortle-berry (a), in moist woods, and about shadowy rocks, in great abundance. The fruit is well tasted, but not to be eaten too freely; being a great astringent, and has been known to cause such a constipation of the bowels as has been fatal \*. It is a succedaneum in the shops to Myrtle-Berries, from which it obtained the name of Myrtillus.
- 18. Procumbent perennial-leaved Worile-berry (b). About moist alpine rocks, and in hilly stony places upon heaths. On the ledges

of the rocks by a fpring at Long-crag, near Watling-street, by the road to Thockrington from Gunwarton. On the moor-edge, by Diligate-hall, near Hexham, plentifully. The root is creeping and woody. The stalks are slender, and branched, from half a foot to a foot in length. The leaves are like those of Box, of a deep glossy green, and alternate. The slowers are on pedicles, in a pendulous cluster at the extremity of the branches, sive, six or seven together, according to the strength of the plant. They are monopetalous, of a cylindric campaniform shape, lightly cut, of a bright white, and sometimes of a pale red; the stamina corniculated, the tube revolute. The fruit is red, of a grateful acid taste. The leaves are bitter. Used in the form of tea, they are accounted good against rheums and distillations of the head.

19. Upright deciduous-leaved Wortle-berry, or great Bill-berry-bufts, (c). In woods, in wet mosfy places. In the Duke of Portland's wood, called the East Common, near Hexham. It is from a foot to two feet and a half high; the lower part naked, very much branched at the top. The leaves are of an ovated form, and in the older and more robust plants pretty long, shining, and full of veins. The flowers are on pedicles, one or two together, cylindric, contracted and reflex at the brims, with four or five denticles, lightly cut. They are white, with a blush of purple. They have eight or ten stamina, four of them corniculated, two of them bending inwards, and the other two straight; the tube thick and cylindric. The ovarium is globose, and four

cornered. The fruit is round and gloffy, of a farinaceous bluishblack. It is esculent, and well tasted. It is full of seeds, in four cells. It slowers in the latter end of May, and sometimes later.

- 20. The perennial-leaved Arbutus, or Uva Ursi, with red fruit (d). In the Duke of Portland's wood, near Hexham, plentifully. I never met with it any where else, except at little Waneyhouse-crag, where I met with one very fine plant of it in a turf-soil among the rocks. It very much resembles the ever-green or perennial-leaved Wortle-berry with red fruit. The stalks are longer, and of a more firm texture, part procumbent, and part upright, according to their age and strength, from a foot to two feet in length. The leaves are also longer, gradually expanding to an ovated form. The slowers are in pendulous clusters on the summits of the branches. They are campaniform; the brims restex and obtuse; the antheræ bicorneous; the fruit round and glossy, of an insipid taste. The calyx is of a purple colour divided into sive parts.
- 21. Yellow flowered, climbing Honey-fuckle (e). In hedges, and thickets. In a hedge by the ford cross North Tyne from Haughton-Strothers to Chipchace. Among the brush-wood in the Roman foss by the 12th mile-stone on the military road, near the Wall-houses. Its usual height is about fix feet. The leaves are of an ovated

form with obtuse points, of a deep green and glossy. The slowers are in large clusters on the tops of the branches, of a bright and beautiful gold-yellow, sometimes with a blush of red. It has a most grateful fragrance. Hence it is admitted into the shrubberries of the genteeler gardens, and often trained to a head for a place among the low Frutices in borders. It is not without its medical virtues. The distilled water of the slowers is commended for inflammations of the eyes. An ointment made of the leaves is used with success in ulcerous tumours of the legs. Against a warm wall, under culture, it holds its leaves in the winter. I found it so in two young plants, in one winter, whilst those in the hedges were deciduous. It flowers in July and August.

22. Upright alpine Honey-suckle (f). In the fiffures of steep rocks. On the rocks under the Roman wall, on the west side of Shewing-sheels, and by crag-lake. It is a low Frutex, upright, and bushy towards the head. The leaves are rough and hairy, but not servated. The slowers are white, and succeeded by two oblong red berries, which as they ripen run into one single striated oval berry, containing commonly about eight feeds. It slowers in July.

23. Woody Night-shade, or Bittler-sweet (g). About moist hedges, and way-sides, by waters. In the hedges about Hexham, Bywell, and

<sup>(</sup>f) Periclymenum rectum quartum, Clus. Hist. p. 59. bene, cum slore & fructu. Xylosteum alterum. Dod. Pempt. p. 412. ex Clusso. and Carbridge. On the banks of the Wansbeck, at Shipwash, among the bushes. By the path to the Bathing-well at Cornhill, plentifully. The flowers are of a beautiful purple, with a yellow tube, in clusters, succeeded by round red berries. It flowers in June and July.

There is a variety of it with hairy Musk scented leaves (h), in the hedges at Drayton, and Crooked Cossham, under Port-sea down, near Portsmouth, in Hampshire; of which I find no mention in authors.

24. Herb-paris, True-love, or One-berry (i). In moist woods. In Cottingwood, near Morpeth, where Dr. Turner observed it \*. At the west end of the rectory-wood at Simonburn, plentifully. The root consists of long bulbous fibres, jointed, and creeping, sending forth new plants at distances. The stalk is round, green, and succulent, ten or twelve inches high, naked to within two or three inches of the top, where are four, and sometimes sive, ovated liliaceous leaves; nervous, and mucronated, of a pleafant green, in a verticillate order. The flower is of a pale yellow and green, variegated. The ovary is nearly outed, and sourcornered. The berry is ripe in the latter end of August, of a glossy

<sup>\*</sup> Turn. Hift. Pl.

bluish-black, not esculent. The feed is contained in four cells. The calyx consists of four patent mucronated leaves, larger than the flower, which hath eight stamina. It flowers in May and June.

25. Tuberous Moschatel, or Musk-Wood-Crowfoot (k). About moist hedges, and on the borders of woods. On the bank under the hedge, below St. Mungo's well at Hall Barns, opposite to the church of Simonburn, close by the brook. Under the bushes by the road on the left hand from Simonburn to Tecket, plentifully. In the hedges about Hexham. The root confifts of bulbous jointed filaments, fending forth new plants at distances. The radical leaves are ternate and lobated, like those of the white flowered alpine fumitory, and of the same pleasant green colour, on a long pedicle. The stalks are smooth, and slender, about four inches high, with a pair of lobated leaves in the middle, on short pedicles. The flowers form a kind of square head at the top, four in a lateral opposite order, crowned with a fifth, each monopetalous cut into four or five fegments, of a yellowish-green colour, smelling faintly of musk. They are succeeded by small greenish berries of a spherical shape. The seeds are disposed on a cornered Placenta, feldom more than three coming to maturity. It flowers in April and May.

26. We have the Arum, Wake-Robin, or Cuccow-pint, both without and with black fpots on its fagittated leaves (1), in wood-bottoms, and

and on moist hedge-banks. It is in great abundance under the bushes in *Chipchace*-island, in a light, mellow, fandy soil, thrown up by floods. The root is said to be detersive and cosmetic, to deface wrinkles, cleanse the skin, and clear the complexion, prepared by drying and powdering, and made into a paste. We are assured by an eminent naturalist that it was thus prepared and used in *Italy*\*; and we are told by another, that it is used by the common people in *France*, in whitening linen †.

27. Lily of the Vally (m). Among the bushes above the scar by the mill at Nether-warden, near Hexham. The fragrant pendulous slowers are succeeded by round berries of a beautiful orange-red, of the size of a common garden-pea. They mostly drop off before they come to maturity with us, which makes them but seldom observed. A green colour is prepared from the leaves with lime, lasting and beautiful ‡.

These are the chief of our Berry-bearing plants. Next of those that bear no berries.

  - ‡ Ex foliis cum calce fit pulcher, et durabilis, Color viridis. Hall. Loco supra citat.

1. Bay-leaved, fweet-scented Willow (n). In moist hedges and meadows, and about ditch-banks. In the Roman fofs between Sherving sheels and Carraw. In the hedge by a streamlet on the fouth fide of their station at House-steeds; and many other places by the Roman wall, in great abundance. The young shoots in May, after a warm shower, are very fragrant. It is frequently the fummer ornament of the pheafant's chimney. The down of the catkin is like cotton, of a beautiful whiteness. Insects terebrate the leaves to deposite their Ova. The organ, with which they perform it, is well described by Malphigius in his anatomy of plants. We find the fame Cuniculi on the leaves of the common willow, and on the twigs of the wild rose, and of the oak. Those of the oak are usually called Oak-apples, from their globose figure and likeness to a small apple, and Oak-galls, from their being tinetorial and giving a black dye. Those of the wild rose are large, of an irregular figure, filimentofe, of a greenish-yellow, tinged with red. The twig of a young white thorn in a dwarf-hedge in my garden had the most remarkable gall-tumour of any I have observed; a villose, filiform matter covering it all round, except at the lateral and terminale buds, fo like the downy coat of that little animal the Mole, that I at first fight fancied it was part of the skin of one, till I raised the bark with a penknife, and found it to be the generative Nidus of an infect; the obstructed juices taking that form on the exterior Cortex through the pores; the hairs being fo many tubes whereby the wounded twig received nourishment from the air and dews; an effort of nature to keep itself from destruction.

Helv. p. 152.

- 2. Myrtle-leaved fweet Willow, Gaule, or Dutch-Myrtle (o). On moist heaths, and about mosses. On the heath between Haly-stone and Harbottle-castle, in great abundance. On the banks of Kimmer lake, near Eglingham. At the former place it is in such quantity, that it is like a little grove, perfumes the air at some distance with its odours after a warm shower of rain or the morning and evening-dews. The wood is sweet-scented as well as the bark\*. It is used in scenting linen.
- 3. Rose-Bay, Willow-Herb (p). Among the rocks and bushes under the Roman wall on the west side of Shewing-sheels, and by Crag-Lake. On the banks of South Tyne, by Slaggiford, in Knaresdale, plentifully. The root is woody, thick, and creeping, of a red-dish-brown colour. The stalk is from two to three feet high, thick, smooth, lightly furrowed, and branched, of a green colour, tinged with red. The leaves are seffile, or close to the stalk, numerous, long, narrow, and pointed, of a lively green. The slowers are large, on bending pedicles of an inch long in the Ala or insertion of the leaves. The Calyx is composed of sour oblong, pointed, purple segments. The Corolla consists of sour

roundish, patent leaves, of a bright red. The stamina are white, with bright brown Anthera. The pistil or style is long and silform, divided at the summit into four parts and reslex, succeeded by a long cylindric pod or capsule, with four valves, and as many cells, for the seeds, which are numerous, oblong, and winged with down. It is preferable to all our rock-plants for beauty. It is so hardy, that many of them grow in the lateral chinks of the taller rocks with hardly any visible earth to sustain them. It is introduced into some of our gardens under the name of the French willow; but being a great runner, it makes a better sigure in its more confined situation among the rocks, than under culture. It slowers in July and August. It is reputed a scarce plant.

- 4. The great, hairy, purple Willow-Herb, or Loofestrife (q), usually called Codlings and Cream, from the smell of the leaves, like Apples and Cream, is plentiful in ditches and by waters. We have it in great abundance in the ditches, and on the ditch-banks, by the mill at Barwesford, on North Tyne.
- 5. The purple-spiked Willow-Herb, or Loosestrife (r). In bogs, and by waters. In a boggy meadow by a streamlet, between two hang-

hanging banks at *Belfay*, near the chapel, plentifully. At the west end of *Halypike*-lake, among the dwarf willows and rushes, sparingly. The root is woody, thick, and divaricated. The stalks are firm, four-cornered, with a blush of red towards the base, very much branched, from a foot and a half to three feet high. There are two, and sometimes three leaves, at a joint, long, narrow, and pointed, of a dusky, green colour. The slowers are hexapetalous, of a strong purple, in verticillate clusters, in the *alæ* of the leaves, in long beautiful spikes. The feeds are yellow, small, oblong, and pointed, in a bilocular capsule.

6. The leffer spiked Willow-Herb, or Loofe-strife (s). In bogs. At the west end of Halypike-lake with the former. On a wet swampy bank on the north side of the river Aln at Denwick, near Alnwick. The stalks are four-cornered, and very much branched, from a foot, to a foot and a half high. The leaves are somewhat broad at the base, and ovated towards the ends, of a smooth lively green. The slowers are in thin spikes, rising from the alæ of the leaves, of a bright purplish-red. Under culture it rivals the former for stature, and out-does it for beauty. The branches are numerous. The slowers also become numerous, in verticillate clusters, on very short pedicles, in tall spikes, making a great shew on the larger borders of slowers and shrubs. It is not a common plant.

- 7. The Hooded Willow-Herb (t), is not unfrequent on ditchbanks, and moist shady places, about Hexham. The stalks are four-cornered, very much branched, and of a weak texture. The leaves are on pedicles, and crenated. The slowers are two in number in the alæ of the leaves, rising erect with a ventricose tube from the calyx, and galeated, of a bluish-purple. The leaves are of a bitter taste, and have the scent of garlic. It is astringent, and was formerly used for wounds and hamorrhages, but is now little regarded. It slowers at the same time with the other willow-herbs, in July and August.
- 8. The yellow Willow-herb, or Loofestrife (u). In shadowy moist meadows, and by waters. By the side of the pond at the southwest end of Wide-haugh, near Dilston, by the road to Hexham, sparingly. On the banks of North Tyne at Low Park-End, near Nunwick, in great abundance. The root is sibrous and creeping, sending forth new plants at distances. The stalk is round, firm, lightly hairy, with a blush of red towards the base, branched at

the top, and from two to three feet high. The leaves are feffile, usually three at a joint, verticillatim, and two on the branches, oblong, and lancolated, of a pale green, and hairy underneath. The flowers are in clusters on the tops of the branches, of a pale yellow, with a circle of pale red in the bottom of each, in the more robust plants. The feed is disposed on a round placenta. The calyx is deeply divided into sive parts. It slowers in June and July. Under culture, in a moist warm border, it grows to between four and sive feet high, and makes a gay sigure with its large beautiful panicles. The leaves were formerly accounted good for cooling inflammations in wounds, but are now distusted.

The leffer yellow Willow Herb, or Loofe-strife, with globose flowers in the Alæ of the leaves, in beautiful spikes (x), does not grow with us that I have observed.

- 9. The Conyza, or Middle Fleabane (y). On ditch-banks, and by waters. On the banks of a rivulet between Segill and Halywell, in great abundance. In a lane leading to the fea-banks from Ellington, near Blakemore-hall, sparingly. We have it also on the banks of Owse-burn, above the bridge, at Newcastle; and in a

Helv. p. 726, 727.

ditch-bottom on the left hand in going up the hill from the Halfway house to Tynemouth. I do not remember to have seen it any where elfe with us. The root confifts of thick bulbous fibres, fending forth new plants at the joints. The stalks are round, robuft, hairy, and glutinous, branched at the top, from two to three feet high. The leaves are of a fagittated form and mucronated, with a plicated undulated margin, very hairy, and glutinous underneath. The flowers are in clusters on the top of the stalk and branches, each on a separate pedicle. They are yellow, and large. The feed is winged with down. The calyx is covered with a fhort down. It flowers in August and September. It makes a very different appearance in different fituations. On: the moist bank by the brook near Halywell, and in the lane near Ellington, the stalks are upright, firm, and robust; the slowers are of a bright gold-yellow, the eye or disk bold and prominent, affording by their numbers a pleafing fight in the harvest-season. On the banks of the Owle-burn, and in the ditch-bottom near the Half-way house, above-mentioned, the stalks are procumbent. the flowers of a pale dull yellow, and the disk but lightly raised; owing to their starved situation, in a wet hungry soil. Under culture on a moist border under a wall it grows to four feet high, the flowers numerous, large, bright, and beautiful, in uniform petiolated clusters, all of a height. But this must be remembered, that it is a great runner, and requires being kept within proper bounds.

10. Great Sea-After, or Starwort (z). In falt marshy places. On the strand at the Ostium of Warn-rivulet, by the ford, near Budle.

On

<sup>(</sup>z) Tripolium. Dod. Pempt. p. 317. Tripolium, Offic. Dal. Pharm. p. 87. Tripolium majus cæruleum. C. B. Pin. p. 267. After maritimus purpureus Tripolium dictus. Raj. Hist.

On the banks of Willington-burn, near the Half-way house, by the Tynemouth-road. The root is fibrous. The stalks are round and robust, from two to three feet high, and branched. The leaves are long, smooth, and lanceolated, of a dark green. The slowers are in clusters on the tops of the stalks and branches, on separate pedicles. They are large, of a light purple, and sometimes white, with a yellow disk. It slowers in August and September. Under culture it grows to four feet high, in a moist soil. It is introduced into the borders of some of the better gardens under the name of the Michaelmas-Aster, and the Michaelmas-Daisie.

- the Oftium of Willington-burn, near Howden-pans. It is usually from a foot to a foot and a half high; in flower at the same time with the former; the flowers more tinged with purple. It holds its distinction of size under culture; and is a pretty plant in its flowering state, in a moist soil. The seed of both these Asters is winged with down.
- 12. Purple flowered Fox-Glove (b). Among the rocks under the Roman wall by Crag-lake, in great abundance. On Fourstone-hills,

and among the rocks at *Tecket* plentifully. It is remarkable, that this plant has not yet been observed through the whole county of *Cambridge*\*.

- 13. There is a beautiful Variety of it among the rocks at the former place (c). It is purple on the outfide, and dotted with purple within, on a white ground, like the former; but the extremity of the fegment is longer, and more elegantly variegated; and the radical leaves are more deeply crenated. Under culture it conftantly holds these two distinctions; and being planted by the side of the other, the difference is obvious to the most common observer in the time of flowering. It is so manifest to our alpine common people where it grows, that they distinguish it by the sine name of the Ladies Finger, whilst they express little value for the common one.
- 14. The white flowered Fox-Glove (d); has been observed to grow in the hedges by the road under Blenkensopp-castle, by the ingenious Isaac Thompson, of Newcastle, Esq; but I have not seen it. It slowers at the same time with the two former, in June and July.
- 15. Nettle-leaved Bell-Flower, great Throatwort, or Canterbury-Bells (e). About hedges, and on the borders of woods, frequent. It flowers

  p. 805.

flowers in June and July. Under culture it makes a handsome appearance with its pendulous flowers, white, tinged with purple, in spikes, in a lateral series; often rising to the height of sive or six feet, with slowers half-way down. It varies in its colour in the woods, sometimes of a pure white, but it does not hold it under culture.

pastures, and on dry hedge-banks. In a field by the lime-kills at Wall, near Chollerford-bridge. In the wood-banks at Nether-Wardon, near Hexham. On the banks of the Tyne, and in the meadows about Bywell. Its usual height is from a foot and a half to two feet. Under culture it rises to three feet high, and sometimes higher. The flowers are of a deep purple, numerous in the alæ of the leaves, and on the tops of the stalks and branches; a single plant sometimes having twenty-nine flowers on the top. It flowers in June and July.

17. Small, simple-stalked, Mountain Throatwort, or Canterbury-Bells, with very short, oblong leaves (g). In Crag-Cose, near Barwesford. It is a pretty variety of the former. It is a foot high, and sometimes less. It has no radical leaves that I can observe. Those on the stalk are very small, and it is not branched. The slowers stand in an upright cluster on the top, compact and neat. It

<sup>(</sup>g) Trachelium oblongo folio alpinum. Boccone. t. 98. p. 70.

flowers in August. It is an elegant little plant. I never met with it in any other place.

- 18. The Giant-Throatwort (h), faid to be plentiful about Shap, in Westmorland\*, does not grow with us where I have been.
- 19. Great white Mullein, High Taper, or Cows-Lungwort (i). On old walls, about houses, and by way-sides. Its usual height is from three to four feet. Under culture it grows to sive or six feet. The slowers are in a long spike, of a beautiful pale yellow. It slowers in July and August. A preparation is made of it for inebriating and taking sishes, which shews it is of a deleterious quality.
- 20. The great Burnet (k), which was long in reputation as a cordial, and an aftringent, but now difregarded, is frequent about hedges, on the borders of woods, and by waters. It

flowers in June and July. The flowers are in short ovated heads, of a reddish brown; beautiful, beyond expression, when held up to the light under a bright sun.

- 21. The leffer Burnet (1) is plentiful in mountainous pastures, especially in a limestone-soil. It is in great abundance in the pasture at Long Rigge, near Nunwick, by the road-side. It is used in the spring for cleansing and purifying the blood, either by insufficion or decoction, or eaten as a sallad. It is a mild and gentle healer of wounds, stops hemorrhages, both internal and external \*.
- 22. Nutant flowered Geum, or purple Mountain-Avens (m). On the banks and strands of alpine brooks, and on the borders of woods, plentifully. We often find it with a beautiful double flower, of the same colour as the single one, purple on the outside, and a pale red within, but it is only an accidental variety, blowing double not above a season. The seed is plumose, and beautiful in the sun.

- 23. Blue-flowered Columbine (n) In Willington-den, by the path to the village from Walls-End, plentifully. In Dilson park, near Hexbam. With its blue flowers the Jellies at great tables used antiently to be coloured. They were thus served up at the royal entertainment of the renowned King Henry V. on his wedding-day \*.
- 24. Great tufted Wood-Vetch, with variegated, fweet-fcented Flowers (o). In the rectory-wood by the brook at Simonburn; also in the banks of wood on both sides of Simonburn-cassle, plentifully. It is remarkable for its lively verdure, and numerous clusters of pendulous flowers, elegantly variegated with purple and white; after a warm gentle shower diffusing a most delightful fragrance; by the help of a bush or a tree growing to the height of seven or eight feet. Extremes of rain and shade are equally enemies to its beauty and scent, appearing then to a stranger as a different species, tetro Odore, as described by Plukinet †, in which state he must have observed it, and not in its perfection. It makes a sine shew under culture, planted against a tree, running up to a great height with its climbers. The feeds, whether rising spon-

taneously about the parent-plant, or carefully sown, constantly produce plants that bear the same beautiful flowers.

- 25. Procumbent Wild Liquorice, or Liquorice-Vetch (p). On dry banks. In great abundance on the brow of a hill, called Cocklehill, at Learmouth, near Cornhill. About the old ramparts at Warkcastle, on the banks of the Tweed, by the road to Carham. In the hilly pastures at Many-laws, under Floddon-hill. In Warden-banks, near Hexham. The root is thick, woody, and divaricated, of a grateful taste, like that of the shops. The stalk is of a lively green, with a blush of red. The leaves are pinnated, ovated, and shining. The slowers are of a pale greenish-yellow. It slowers in July. The seed is reniform.
- 26. The annual, climbing, white flowered Funitory (q), grows plentifully about a large rock above Tecket-water-fall; also among the rocks at Little Waneyhouse-crag. It flowers in July and August.

- 30. White Horehound (u), used for assume and pulminary complaints, grows abundantly on the sea-banks, by the road near Bambrough-castle. I have not observed it any where else with us.
- 31. Virvain (x). By high ways, and about houses. At Bywell, plentifully. It is accounted a nervine and cephalic. The Roman priesthood wreathed their brows with it at their solemn festivals, and perfumed their altars with its ashes\*. It was in no less veneration with the British Druids.
- 32. Nep or Catmint (y). On dry banks, about hedges. In the hedge in the west-lane under the bank of wood at Nether-Warden; also in the hedges about Hexham, but not very common; in flower in June and July.

33. We

- 33. We have Wood-Sage (z), in great abundance about shadowy rocks, and on the borders of woods. It is sometimes gathered and fold by the common herbarists for the true Scordium, to which it is accounted no bad Succedaneum. It is an uncommon plant in some parts of England, especially in Cambridgeshire.
- 34. English Sea Wormwood (a). On a projecting, cavernous searock near Howick, called Rumble-Churn, from the noise of the currents under it. At Holy Island, where Dr. Turner observed it \*. It is commended as a plant of extraordinary virtues, yielding an aromatic oil, a volatile and fixed salt, of great use in hysteric, hypocondriac, and hydropic cases †. Insused in ale, it gives it an aromatic flavour, and is good for the scurvy and dropsy, and for all diseases caused by the coldness of the liver, or want of digestion ‡.

flender, and of a yellowish-white. The stalks are round, firm, and branched, from a foot and a half to two feet high. The leaves are large, deeply laciniated, and of a bluish green. The slowers are large, on the tops of the stalks and branches, of a bright and beautiful yellow, as intimated by Catullus.

Ore floridulo nitens
Alba parthenice velut
LUTEUMVE PAPAVER.

The calyx is bifoliate. The feed is reniform, disposed in long pods or bilocular capsules, divided in the middle by a thin membrane.

For the effects of this plant taken inwardly, I refer to Mr. Newton's account of it in the Philosophical Transactions; very diverting, if he was not imposed on by his Cornish-host, and the Plebeians from whom he had it, who sometimes put a rustic jest on the inquisitive and curious stranger\*. It slowers in June and July.

43. Sea-Holly, or Eryngo (k), does not grow with us where I have been.

- 44. Common Eryngo (1). Between the Glass-houses and Dent's Hole, near Newcastle. The root it about a foot in length, of the thick-ness of one's singer. The radical leaves are six or eight inches long, deeply divided, as it were, into so many lobes, serrated at the edges, the denticles ending in very sharp prickles. The stalk is striated, round, tough, and branched, usually two seet high, with alternate amplexicaule leaves like the radical ones, of a bluish-green. The flowers are small, in roundish umbells on the tops of the stalks and branches; each flower consisting of sive whitish petals; and each petal, for its security, guarded by a sharp prickle. The root candied with sugar, and dried, is used as a pectoral by decoction. It is a scarce plant in most counties, notwithstanding its name.
- 45. Sampire (m). On the fea-rocks near Alamouth, plentifully. The root is oblong, and of an aromatic taste. The radical leaves are large, divided into numerous oblong, narrow, pointed, and thick fegments, of a deep green, succulent, and of a saltish taste. The stalk is ten inches high or more, round, thick, and very much branched. The slowers are yellow, in large umbels. It is used as a table-pickle. The ingenious Mr. Evelyn admired it as a sallad.
- 46. Thrift, or Sea-Gilliflower (n). At Dunftonbrough-caftle, on the fea-banks, where there are great varieties of it; the most beautiful.

tiful with bright red flowers, fometimes taken into gardens for edgings. It flowers in August and September.

- 47. Orpine, or Live-long (o). About hedges, and in pastures. In the fecond field on the left hand from Simonburn to Nunwick, plentifully. At Rodbam, about the hedges, sparingly. The stalks and leaves are succulent, of a bluish-green, frequently with a blush of red; the leaves ferrated; the slowers in a kind of umbel, large, and of a beautiful purple. Its usual height is from a foot to a foot and a half in its wild state, and from two to three feet under culture. It slowers in June and July.
- 48. Sharp-pointed-leaved Stone-crop (p). On old walls, and about rocks. On an old wall at Lipwood, near Hayden-bridge. On the rocks by Tecket-water-fall, on the north fide. Under culture it has the appearance of a foreign plant, as if it lived under a warmer fun. If it was less frequent, it would certainly be introduced into flower-borders, among the more humble plants,

- 52. Meum, or Spignel (t). On a hill by the village of Thockrington, on the north fide of it; where it is called Hook-a', and the hill Hook-a'-hill, by the common people, from the frequent hooking or digging of it up for use. The root pierces deep into the ground, of the thickness of a man's finger, brown on the outfide, and white within, with a tuft of fibres of decayed leaves at the crown. The radical leaves are on long pedicles, large, divided into numerous, oblong, capillary fegments of a deep green, foft in handling, and pleafant to the eye. The stalks are round, firiated, and branched towards the top, with leaves like the radical ones, but finaller, and alternate. The flowers are white, in umbels. The feed is oblong, striated, and of an aromatic finell, when dried. It grows in great abundance upon this hill, but no where elfe with us that I know of. In the fields about two miles from Sedberg by the road to Orton, in Westmorland, it is faid to be in great plenty, where it is called by the common people, Bald-money; also at Longwell, in Selfide, about three miles from Kendal, and in feveral other places in that county \*.
- 53. Alexanders (u). In gravelly places, and about rocks, near the fea. On a gravelly bank at the Offium of Willington-burn, near Howden-

Howden-pans. On the fea-rocks at Tynemouth-castle. The root is moderately large, white, and acrid. The stalk is robust, round, jointed, striated, and branched, three or four feet high. The leaves are pinnated, and serrated at the edges. The slowers are of a greenish-white, in large umbels. The seed is large, black, and striated. It is a scarce plant. Both the roots, young shoots, and leaves, are used as a fallad in the spring with vinegar and sallad oil; the roots sometimes boiled; very nourishing; good for the scurvy; and, according to Boerhaave, for the asshma. It slowers in June and July.

54. Smallage (x), the leaves of which are like those of Alexanders, but not so large, is not unfrequent by flow running waters and springs in shady places. It is an excellent remedy for the dropsy, boiled in small ale. I have known an eminent cure done by it in the south of England. The person cured was a young woman of twenty-eight years of age. She was reduced to such weakness that she could not sit up in a chair, and refusing to be tapped, her death was daily expected; when a person of great medical experience accidentally hearing of her case, out of mere humanity recommended the use of this simple remedy, whereby

in a week's time she found herself better, and in a few weeks more was perfectly recovered, and never, for these twenty years past, had any return of it, continuing in a good state of health; at this time, I believe, alive and well. It slowers in June and July.

on the banks of North Tyne at low Park-End, near Nunwick, in a bed of water-fand, thrown up by floods, among the bushes. The root is of the thickness of the common hemlock, oblong, white, and fibrated. The stalk is round, striated, and branched, three or four feet high. The leaves are pretty much like those of smallage, but longer, and more deeply divided. The slowers are white, in large umbels. It flowers in July and August. It is of a deleterious quality, and in the spring has been too often gathered and eaten by mistake for Smallage, and proved fatal. We have some dreadful accounts of its poisonous effects in authors \*. The root is more poisonous than the leaves; and it is remarkable, that though it kills both men and horned cattle, horses eat of it without danger †.

fimples, is plentiful by water-courfes, about bogs, and in damp woods. It is in great abundance among the bushes by the streamlet on the fouth fide of the road near Nunwick-mill; also in the rectorywood at Simonburn. We are told by the learned Fabius Columna, that with a dram and a half of the powder of the root (pulled up before it fent forth the stalks) taken in wine, water, milk, or any other proper liquid, he cured not only himself, but others, of the epilepfy, by once or twice taking; to infants, and those of tender years, feized with convulfive fits, he ordered it to be taken in milk, who, by the relation of their friends, were, with God's bleffing, perfectly cured\*. We are affured by the late Cambridge-professor, Mr. Martyn, F. R. S. that he had seen it used with great fuccess for the hysteric passion, and for violent paroxysms of the asthma. The method was to boil an ounce of the roots in a pint of water, to let it stand off the fire close covered till it was cold, and then take draughts of it in a glass. gives a preference to the wood-plants to those that grow in watry places †. The famous Haller feems to have a less opinion of its

pure white; and the latter male-flowers, pretty large, of a bright white, with a blush of red; in neat umbels. They flower in May and June. The last is plentiful in a bog under bushes near the Osium of the brook below Nunwick, from five to nine inches high; the first in another by the Osium of the brook at Wark, on the fouth side, from nine to fourteen inches high. Culture makes no alteration in them.

60. Great Burnet Saxifrage (f). In dry pastures, and on banks about hedges. Under the hedges at Fair-show and Long-Rigge, near Nunwick. On a gravelly bank, on the north-east side of the bridge at Barwesford, near Chipchace. The root is oblong, white, and acrid. The stalk is round, striated, sistulous, and branched, two feet high. The leaves are simply pinnated, each composed of a double row of ovated, serrated foliola, on pedicles, joined to a middle rib, with an odd leaf at the end. The slowers are white, in umbels, moderately large. It slowers in June and July. It is of an acrid, but not unpleasant, taste. It is much commended as a pectoral or stomachic by the Germans, especially the followers of Stabl, and, according to Haller\*, deservedly.

- banks. In the rectory-den at Simonburn, plentifully. The root is oblong, very flender, white, and acrid. The stalk is round, striated, and branched, sparingly set with leaves, divided into sive long segments. The radical leaves are simply pinnated; the folioles in a double series on two sides of a pedicle, with a single leaf at the end, roundish, crenated, and of a dusky green colour. The flowers are white, in umbels. It slowers in July and August. It is one of the ingredients in the Pulvis Ari compositus of the shops. The common herbarists frequently gather the root of the small Sanguisorba for it.
- 62. We have the Mountain-Saxifrage, with finely-divided leaves (h), in the fame den, under the road to Tecket, sparingly. It flowers at the same time with the former; of which it is a variety. The petals are revolute, or turn up, and bend inwards; which makes them seem as if they were cut.

- 63. Meadow Saxifrage (i) is plentiful in moist meadows and pastures. The flowers are in umbels, of a yellowish-white. Each flower consists of five petals, almost equal and entire. They are hooked or turn inwards at the ends, which makes them appear as if they were notched. The feed is thick and large, with three stria so remarkably deep, as to make it seem alate, or winged. Both it and the root are used for the gravel. It flowers in June and July.
- 64. Bastard-Stone-Parsley (k). On ditch-banks. On a gravelly bank by the road on the south-east side of the bridge at Barwes-ford; also in the lane between the Edge-house and Chollerton-road. The flowers are white, in umbels. It flowers in July and August. the seed is very small, brown, and striated. It is put to the same use as the former.

Tuber, or bulb, lies deep in the ground; brown on the outfide, and white within, of an irregular roundish shape; of a grateful taste, wholesome and nutritive.

- 66 Yellow-flowered Tragopogon, or Goats-Beard (m). In meadows, and in flony places, by waters, plentifully. It is one of those plants which, by an invariable law in nature, performs its conflant Vigiliæ, by closing its leaves about noon. From which remarkable property the common people call it, Go to Bed at Noon. The root and young shoots are esculent, of an agreeable taste, without any acrimony or viscidity, very nourishing. It flowers in July.
- 67. Purple-flowered Tragopogon, or Scorzonera (n), does not grow with us, but as it may have escaped out of gardens.

- 63. Blue-flowered Mountain Sonchus, or Sow-Thiftle (o). On the borders of corn-fields about Willington and Howden-Pans, sparingly. Its usual height is from three to five feet. The flowers are on villose glutinous pedicles, in a long spike, of an elegant blue colour. It flowers in July and August. The feed is ovated and compressed, with three strice or furrows, and winged with down.
- 69. The great, English, soft, or gentle Thissle, or melancholy Thissle (p), is common in moist alpine woods and meadows. The stalk is very handsome, gradually tapering from the base to the top, from two to three feet high. The slower is large, of a bright purple. The calyx is imbricated. It slowers in June and July.
- 70. The purple-flowered dwarf Carline Thiftle (q) is not unfrequent in mountainous pastures, and on dry banks. The leaves are disposed

disposed on the ground in the form of a circle, on pedicles, semipinnated; the pinnules sometimes with two, and sometimes with three, lobes, serrated, and ending in sharp spines. The stalk is hardly an inch long. The head is very large, and long with brown, triangular scales, shining, and not prickly. The seed is a little hooked, and winged with down, about two inches long.

71. We have the elegant woolly-headed Thiftle (r) about the hedges under the hill by the church at Wall's-End, near Newcaftle, fparingly. The stalk is firm, of a man's height, and branched. The leaves are very large, a foot or more in length, rough, succulent, and downy underneath, semi-pinnated; the pinnules long, with two lobes, the nerve of each lobe ending in a robust spine, the terminale spine longest. The slower is purple, long, and bending. The heads are very large and spherical, with acute upright scales, covered with a sine silk-like down, each scale terminated with a yellow prickle. The seed is white,

compressed, almost oval, and obliquely truncated. The placenta is esculent, as is the stalk, wholesome and nourishing.

72. The elegant purple-flowered Ladies Thiftle (s) is plentiful in the lane at Tynemouth, leading to the church, very near the village. I have observed it also under a hedge on the banks of the Tyne by the Ostium of Willington-burn, on the west side, near Howden-pans. I have not seen it in any other parts with us. The leaves are very large, with an undulated, plicated margin, variously serrated, the denticles ending in sharp spines, of a deep glossy green, the nerves milk-white, which give it a beautiful appearance. The stalk is from sive to six feet high, firm, and branched, The slowers are large, of a bright purple. The calyx is armed with robust prickles. It slowers in July and August. The feed is used by emulsion for acute pains and diseases of the breast with success\*; especially for that kind of pectoral rheumatism which is faid to be sometimes consounded with the pleurify.

Two drams of it infused in six ounces of the distilled water of its leaves effects a cure †.

73. The purple-flowered, nutant Musk-Thistle (t), which is one of the most common thistles by way-sides and in waste places in some of the fouthern counties, especially about Cambridge, but not about London, is very rare with us, except about Newcastle, between the Glass-houses and Dent's-hole, where it is in great plenty. It slowers in July and August. The slowers are very large, and pendulous, of a bright purplish-red. The calyx is armed with yellow prickles, exceedingly sharp and robust. The feed is of a light brown, smooth, and glossy, crowned with hairs. It has a faint scent of musk, very perceivable about the time of slowering.

74. The procumbent, purple-flowered Star-Thiftle (u), which is plentiful on wastes, and by high-ways in many of the southern counties,

counties, is only observed to grow with us in the same place with the former. The stalk is usually from a foot to two feet in length, and branched. The leaves are soft, very hairy, with a broad nerve, and pinnules at distances, long, lanceolated, and moderately cut, or laciniated, not prickly. It slowers in June and July. The slowers are of a lively purple. The outer florets are disposed in the form of a radiated circle. The calyx is imbricated, and armed with rigid spines. The feed is cordiform. It is used with success at Paris for urinary obstructions; one dram infused in a glass of white wine. The exterior Cortex of the root, gathered about the end of September, dried in the shade, and sinely powdered, is likewise used there in the same manner, and in the same quantity, for an intermitting sever, on the approach of the sit. The root was formerly used by other foreigners as a succedaneum to the Eringo-root †.

75. The purple-flowered Saw-wort (x), is fcarce with us. A plant of it was found at West-Dibden, near Hexham, with the Chamarubus;

from which I have a thriving one under culture from a flip of it. The stalk is slender, from two to three feet high, and branched at the top. The leaves are firm, smooth, and serrated at the edges, sometimes simple and ovated, and sometimes with acute semi-pinnules, the terminale one largest. The calyx is cylindric, elegantly imbricated, and smooth. The slowers are in a kind of umbels; composed of uniform purple florets. The feed is crowned with hairs, of a brownish shining yellow. Few of them seem to arrive at a secundating state, especially those that are very small, which may be the reason why it is such a scarce plant with us. It slowers in July and August. It is tinctorial. A sine yellow is drawn from it, which is very much valued. It is, therefore, like other tinctorial plants, sit for wounds. It is commended for those that are occasioned by falls, and for ruptures, but it is feldom used.

76. The Golden-Rod (y) is frequent on the strands of alpine brooks, and about rocks. The root is sibrous. The stalk is from a foot to three feet high, and branched. The bottom-leaves are usually ovated and serrated; the upper ones ovated and lanceolated, firm, hairy, and crenated, on pedicles. The slowers are in spikes, at distances, of a pale shining yellow. The slorets, of which they are composed, are few and large. The tube is bicorneous. The semi-slorets have three nerves with a contracted apex, cut into sive or ten parts. The calyx is of a pale shining

green. The feed is conic, and striated, with an acute base, and a round, plumose crown. It slowers in August.

77. There is a VARIETY of it with purplish Stalks, and firm lightly ferrated Leaves, of a smooth pleasant green (z), among the furz on Four-stone-hills, and among the rocks under the Roman wall by Crag-lake.

It is aftringent and bitter. It is used by decoction for internal bruises, and outwardly in an ointment for wounds. For old putrid fores and ulcers it is excellent, cleansing and healing them. A great cure was obtained with it in an ulcer of the *Urethra* by an ingenious foreigner, which is mentioned with respect by the learned *Gottenberg*-professor, who calls it—pulchram Sanationem \*. Three drams of it, powdered fine, and taken in a convenient liquid three times at due intervals in eight hours, helps persons afflicted with the stone, whom it sometimes has cured by bringing it away †.

- 78. Round, white-flowered, Mountain-Cudweed, or Cat's-foot (a). On dry alpine heaths. At Temple-Green, near Wark, in Tynedale. On a dry bank near Thockrington by the road to Watling-street. On Etallmoor, by the road to the coal-work, plentifully. It grows after

the manner of the garden-daify, in tufts, with procumbent stalks which take root at the joints, and send forth new plants. The leaves are oblong, indented at the edges, with a nerve through the middle, and pointed; of a smooth deep green on the upper part, and hoary underneath. The slower-stalks are three or four inches high, round, and hoary, with short, narrow, pointed leaves. The slowers are at the top, in a kind of umbel, each on a separate pedicle, the largest in the center, of a bright white; the disk sometimes adorned with a beautiful blush of red.

- 79. Round, purple-flowered Mountain-Cudweed, or Cat's-foot (b). At Temple-Green, with the former, by the road-fide. The flowers are of a bright purplish-red, neat and compact. They retain their beauty under culture.
- 80. The long white-flowered Mountain Cudweed, or Cat's-foot, is plentiful with the two former. The stalks are taller, and not so firm, The slowers are less elegant. They are long, irregular, and of a dull white; though they are all of the same family, and distinguished only by their sex; the two sirst bearing male, and this semale flowers (c). They are called Everlasting slowers by our shepherds and common people on the wastes, from their holding their colour after they are gathered. The flowers of the two sirst

are as beautiful on the stalks at two year's end, as in the time of flowering, if gathered dry, and kept free from dust. They flower in May and June. The feed is minute, with a plumose crown. The leaves are used for defluxions of the lungs, and for the convulsive or whooping cough in children.

81. Purple-flowered Yarrow, or Millfoil (d). By way-fides, and on new ditch-banks, not unfrequent with the white fort (e); of which it is a variety.

The common Yarrow is commended for internal hæmorrhages, and defluxions of all kinds. It is an excellent remedy for stubborn cancers, with garden hyssop; an equal quantity of both pounded together, and a spoonful of the juice drank in a glass of white wine every morning fasting. A young gentlewoman in the south of England, of about thirty years of age, had a cancer in her breast, so dangerous, that nothing less than amputation, it was thought, could save her life; which she declining, a gentleman of great medical experience, and of a humane disposition, recommended the use of this simple remedy, by taking

hand of the road to Chipchace, in great abundance. I never obferved it in any other place with us. The root is composed of tuberous or knobby fibres. The stalks are striated, sistulous, and naked to the top, from a foot to two feet high. The leaves are long, pinnated, and serrated at the edges. The slowers are in an umbellated panicle; each usually composed of six orbiculated petals, of a bright white, and often with a beautiful blush of red. The calyx in its maturity is reslex, and divided into six parts. It slowers in June and July. Under culture it grows to three feet high, and is branched at the top. The root is astringent, aperient, and diuretic. It was formerly in good account for the hæmorrhoids, but now rarely enters into use.

85. Melilot (m). On the banks of the river Wansbeck, by a grind-flone-quarry, near Ashington. By the path to the bathing-well at Cornhill, near a streamlet. The stalks are firm, sistulous, and branched, from two to four feet high. The leaves are ternate, oblong, and serrated at the edges, of a deep shining green, on pedicles. The flowers are of a pale yellow, in a pendulous late-

ral feries, in spikes. It flowers in July and August. On the warm fertile banks of the *Wansbeck*, it is robust, tall, and thriving. By the streamlet at *Cornbill*, it is slender, short, and meager, owing to the sterility and coldness of the soil.

It is an acrid, bitter plant, but of no difagreeable odour. The distilled water of the flowers being mixed with other aromatic waters, has the remarkable property not only of retaining, but of increasing their scent\*. It is used in the sweet-scented water at Paris, called Eau de Corduë†. The flowers give ease, by infusion, in cholic-pains, and inflammations of the bowels‡. The leaves are in most frequent use as an emollient in external applications, especially for painful tumours, and wounds difficult to heal.

86. Strawberry-Trefoil (n). On the banks of Halypike-lake, plentifully.

87. Annual, Hare's-foot-Trefoil (o). Ondry hedge-banks, and barren places. On an old hedge made up of earth and flone by the road

plant 4, is frequent about the roots of trees in woods, and under damp hedges. The leaves are verticillate and stellate. The slowers are milk-white, monopetalous, cut into four segments, and cruciform. The feed is hooked at the end, set with hairs. It flowers in May. It is used by infusion for inflammations occa-sloned by falls, and for wounds. The slowers in a conserve are commended for paralytic complaints.

95. Enchanter's Nightshade (y) is plentiful under trees on woodbanks. It is in great abundance by the Ostium of Goston-burn, on the north side, near Wark, in Tynedule; also at the west end of the rectory-den at Simonburn. The root consists of white, jointed, succulent sibres, sending forth new plants at distances. The stalk is round, slender, and branched, from a foot to two feet high. The leaves are in pairs, on long pedicles, lightly hairy, nearly cordiform, sometimes indented at the edges, and sometimes not, and sometimes undulated, of a pale green. The slowers are in pairs, in the alæ of the leaves, on pedicles, in thin spikes. They are dipetalous, small, and white, sometimes with a blush of red. The calyx is of a reddish-green. The feed is bilocular. It slowers in May and June. The leaves are used in an ointment for the hæmorrhoids \*.

I have not observed the lesser Enchanter's Nightshade, with small, cordiform, and deeper-servated Leaves (z), to grow with us.

bushes on dry banks, and on the borders of woods. Its flowers in July and August. It is eminently astringent. The flowers are so turgid with a red fluid, that by distillation they yield an oil like a resinous balsam. Hence it stands in the first class of vulneraries. For its extraordinary power in helping weak nerves, it obtained the name of Fuga Damonum. An essence of the tops of it, with essence of Yarrow or Milsoil, is a celebrated sebrifuge, a great restorer and strengthener of weak spirits; and of great fervice to those who are under assistance from worms \*. It is commended for ulcers in the kidneys by decoction, cleansing and healing them. A decoction of the slowers is advised for disorders of the lungs †. An infusion of them in sallad-oil is an antient and approved remedy for wounds.

97. Small, procumbent, perforate St. John's-wort (b) is less common. I met with it under the bushes by the brook at the west end of the

Prioris (Tragi) satis adfine est, caule sub floribus longe nudo, raris soliis, solia maxima, ovata, & ex ovatis acuminata, non persorata, ora insignita serie propria punctorum nigrorum. Flores similes, sed pauciores, in umbellam aphyllam congesti. Calycis soliola serrata, quovis dente terminato globulo resinoso: sub quavis anthera globulus ctiam niger.

<sup>\*</sup> Raj. Syn. loco citato.

100. Hairy perforate St. John's-wort, or Tutsan St. John's-wort (e), is plentiful under the trees in damp woods. Among the moist rocks by the brook below Tecket it grows to the height of three or four feet. It slowers in July and August.

bogs in woods, pastures, and the moist strands of brooks. It is in great abundance at the south end of the pasture on the north side of the rectory-house at Simonburn, also in a bog under the bushes by a spring at the west end of the rectory-den, at the same village. It is a beautiful plant under culture. It slowers in July and August.

I have not observed the procumbent hoary-leaved St. Peter's-wort. (g) to grow with us.

island, in great abundance, in a light sandy soil, fertilized by floods. The stalk is procumbent, taking root at the joints, slender, lightly singed with red. The leaves are on short pedicles, ovated, and sparingly lanceolated; in which lies the difference between it and the yellow-slowered *Money-wort*. The slowers are monopetalous, in pairs on short pedicles, of a beautiful yellow. The calyx is divided into sive stellate segments.

105. Annual scarlet-flowered Pimpernel (1). In corn-fields. In the fields about St. John-lee and Hexham, plentifully. The stalks are slender, square, and branched. The leaves are ovated, and sparingly lanceolated. The flowers are in pairs on pedicles, of a bright and beautiful scarlet. The calyx is deeply divided into five acute segments, of the same colour. The tube is short and white. The stamina about the tube are bearded, and crowned with summits or antheræ of a bright gold-yellow. It slowers in June and July.

106. Annual blue-flowered Pimpernel (m). Among corn, but not common. In the corn-fields about Alnwick, sparingly. In its whole form

much branched, and woody, usually about four inches long. The leaves are firm, smooth, and of a lively glossy green. Culture makes no change in it. It flowers in July and August.

109. Male Speedwell, Fluellin, or true Paul's Betony (p). In woods, and about shadowy rocks. Among the rocks under the Roman wall on the west side of Shewing sheels, and in Ramshow-wood, by the road-fide, plentifully. The stalks are mostly procumbent, firm, hoary, and taking root at the joints. The leaves are in pairs at the divarication of the branches, moderately firm, liairy, ovated, and crenated at the edges, of a pale green. The flowers are in spikes. They vary in their colour; fometimes of a pale blue, with red or blue veins; fometimes white, with red veins; and fometimes entirely white. They are monopetalous. The ovary is cordiform and compressed. The seed is roundish and yellow. It is an aftringent and bitter plant. It is used by infusion for defluxions from the head in great colds, coughs, and difficulty of breathing, and all difeases of the breast and lungs, with just commendations\*. Two ounces of the juice drank at a time, and often, is advised for alleviating the anguish and torture of the gout †. The Thime-leaved, Female Fluellin, or Paul's

den, at the east end. It flowers in July and August. It is also a variety of the former, and differs from it only by its low stature, bushiness, and brightness of its flowers. The common fort is used with great commendations in intermitting fevers, by infusing a handful of the tops of it in white wine, or giving a dram of the extract of it with as much powder of Jesuits bark, when there are obstructions in the bowels, which cures without any return \*. It is used by infusion in a glass of white wine as a pectoral, to give appetite, and for disorders occasioned by worms, but it is not an agreeable draught, which makes an extract from it to be commonly preferred.

124. Yellow Centaury (k) is frequent in the dry hilly pastures about a quarter of a mile west from Honeyclugh-crag, near Chester-wood and Whinetly, on South Tyne. It slowers in August. The slowers contain a yellow sluid which by distillation yields an oil like a resinous balsam, like that mentioned of St. John's-wort †.

125. Blue-flowered annual, autumnal Gentian, or Felwort (1). In dry mountainous pastures. In Crag-close, near Burwesford, in great abundance. It flowers in September.

126. There

is in great plenty on Broadpool-common, and in the pastures at Goat-stones, by Raven's-hugh-crag, near Simonburn. The root is sibrous, and sends forth many stalks; four, but rarely sive, inches long; frequently procumbent from their weakness. The under leaves are round and sirm; the upper ones narrow; both of a lively green. The slowers are in spikes, in a lateral series, for the most part of a beautiful blue, sometimes variegated with white in elegant capillary lines; holding their colour in drying. It is a very bitter plant, and retains its bitterness a long time.

- 134. Long-leaved Sun-Dew (u) is frequent in marshy places in woods, and about bogs. It is in a bog on the north side of Slater-field, near Simonburn, plentifully.
- Duke of Portland's wood near Hexham. They are both low plants, about four inches high. The flowers of both are in thin spikes, on pedicles. They are small, of a bright white. They have the name of Sun-Dew from the drops of a clear fluid standing always on their red hairy leaves in the hottest day. They are so fatal to sheep, that the common people call them, the red Rot; owing to vermicular Ova inserted in the leaves, which secundate

land-Oeconomy it is of frequent use. To sheep it is very hurtful. Goats, horses, and horned cattle will not eat of it †.

138. Round-leaved Winter-green (z). In woods, and upon heaths. On the edge of the moor by Dilligate-Hall, near Hexham. In the Duke of Portland's wood, and in other woods, near that town. In the bank of wood opposite to the west-end of the Rectory-den, at Simonburn, on the north-east side of the freestone quarry. On the hedge-bank by the road up the hill to Simonburn-castle, near a small spring. On the borders of Ramshow-wood, by the way-side, near Wark, in Tynedale, plentifully. The root consists of white, succulent, or bulbous sibres; slender, divaricated, and jointed, sending forth new plants at distances. The leaves are roundish, with an obtuse point, firm and smooth, on long pedicles. The stalk is sive or six inches high, or more, angulated, and naked more than half way up. The flowers are in a thin spike, on short bending pedicles. They are campanisorm, of a bright white, sometimes with a blush of red.

It varies in the form and fize of the leaves. Those on the moor by *Dilligate-Hall*, are nearly orbiculated, thick, fucculent, and of a gloffy green, often two inches and a quarter long, on pedicles of the same length. At all the other places they are

firm, fmaller, rather oblong than orbicular, with an obtuse point, and sometimes lightly ferrated. It slowers in June. The tube is incurvated or hooked. The stamina are reslex or turn up to guard the ovary.

139. Small Winter-green with roundish serrate-leaves (a). On the borders of Ramshow-wood, by the road-side, with the former, plentifully. I never observed it in any other place. The leaves are roundish, mucronated, sirm, and lightly serrated. The stalk is from three to four or sive inches high, and of the same shape as the former. The slowers are in a short spike, close and compact, of a bright white, and always with a beautiful blush of red. The tube is short, straight, broad at the end, and divided into sive parts. The stamina are revolute or bend inwards, to protect the ovary. It slowers at the same time with the former.

The leaves of both kinds are aftringent. They are used for wounds and bruises, by decoction, insusion, fomentation, or in an ointment. They are commended for ulcers in the breast.

140. Winter-green, with Chickweed-flowers (b), faid by Mr. Ray to grow among the bushes in mountainous places north of the

Roman Wall, has been much fought for by myself and others, but hitherto in vain.

141. Perfoliate-grass of Parnassus (c). In moist fandy places, and about bogs. On the fea banks, called the Links, between Druridge and Cresswell, composed of drifted sea-sand. On the strand at the east end of Bromley-lake, plentifully. The root confiss of finall perennial fibres. The leaves are cordiform at the base, and amplexicaule, pointed at the ends, of a pale green colour. The flalk is five or fix inches high, flender, and angulated, with a fingle leaf. The flower is moderately large, composed of five white petals, with numerous beautiful veins. The antheræ are elliptic and compressed, with sphærical yellow summits. The younger stamina closely embrace the ovary; the older ones are expanded. The ovary is conic and four-cornered, with four valves, and a kind of biatus on the apex, but no tube. The feed is yellow, oblong and numerous, disposed in a single capsule on four placenta's, parted half-way by a membrane, without an axis, as in the poppy. The calyx is composed of four folioles, shorter than the flower. It flowers in August and September. The leaves and the roots were formerly commended in a decoction or infusion for diseases of the eyes, and obstructions of the liver, but are now difregarded.

west end of the Rectory-Den at Simonburn, plentifully. The root is a small, succulent, round bulb. It sends forth two leaves, eight or nine inches long, half an inch broad, and ribbed lengthways. The stalk is angulated, eight inches high, with two small narrow leaves near the top. The slowers are stellate, on pedicles, in a kind of umbel. They are green on the outside, bordered with yellow, and of a fair yellow within. The tube is a triangular prism; the stigma divided into three parts. It slowers in April and May. The slowers are very beautiful under a warm sun, being then reslex; but are expanded at other times, except in cold, cloudy, or haizy weather, and at night, when they close till the morning, and sun-shine appears.

143. Little purple-flowered Orchis (e). In Crag-close, near Barwes-ford. The flowers are in a very short, compact spike, elegantly

next the fields, fparingly. The flalk is flender, from fix to nine inches high. The flowers are in a thin spike, of a uniform bright purple, and sometimes with two different shades, lighter and deeper, of a high fragrant scent, which it retains under culture. It flowers in July.

- 147. Sweet-scented Buttersty-Orchis, or Satyrion (i). In mountainous meadows, frequent. The flowers are white, with a yellowish tinge; the spur an inch, or an inch and a half, long. They are in a thin spike, and of a grateful smell. It flowers in June.
- 148. There is a VARIETY of it on the borders of mountainous woods, and dry shady banks, with tall spikes of bright white odoriferous flowers, and a longer spur, from an inch and a half to two inches; the stalk often a foot and a half high; the leaves next the ground remarkably large and broad (k). It is not unfrequent on the borders of Ramshow-wood, by the way-side, near the mill. It is also frequent on the dry shadowy banks by the streamlet below Honeyclugh, near Chesterwood. It retains its beauty and grateful fragrance under culture. It slowers in June and July.

149. Small, autumnal, fweet-scented, yellow-slowered Orchis, or Monorchis (1). At the north end of Crag-close, near Barwesford. The root is a single sphærical bulb, more sirm than those of the other orchis's. It sends forth two and sometimes three leaves. The stalk is slender and naked. The slowers are of a pale greenish yellow, of a grateful sweet odour. Three of the petals of each slower are simple and roundish? Two others, and the lip, are cruciform. There is no spur.

150. Autumnal Psuedo-Orchis (m). In the same close, with the former. The roots consist of cylindric, bulbous sibres. The leaves are obtuse and elliptic, even those on the stalk. The slowers are in a long compact spike, of a pale yellowish-green, with very short tumid spurs, and have no scent. The three larger petals of each are white; the two smaller ones of a greenish-yellow. The beard is like that of the Monorchis, divided into three parts.

a divaricated bulb, elegantly imbricated. It is white, with a bluish tinge. It fends forth one, and fometimes two or three stalks, from four to fix inches high, thick, round and succulent, of a light purple, with a few oval ferrated membranes on the lower part, instead of leaves. The flowers are monopetalous, and bilabiate. They are in a spike, in a pendulous lateral feries; commonly in pairs, with one between each pair, of a beautiful flesh-colour on their first appearance, on short white pedicles, not eafily feen for a broad white pointed membrane on the back of each, fmooth and gloffy. The calyx is campaniform and divided into four parts, of a flesh-colour, with a short white down upon it, as is on the flowering part of the flalk. The ovary is compressed, ovated, pointed, and uni-locular. The seed is of a greyish-black, roundish, and numerous, disposed on a placenta. In its older state it assumes a less gay appearance. The stalk is then of a languid purple, and the flowers of a dull white. It flowers in April and May.

I have not observed the bulbous, seven-leaved Dentaria, with sive black clustered berries in the alæ of the leaves (a), to grow with us.

being used by artificers for polishing, and said by a late learned and

Sheels,

sheels, plentifully. In Grinden-lake, sparingly. It slowers in July and August. It raises its head in a gradual expansion above the water about feven in the morning, and about four in the afternoon finks down again to its former station, into a state of rest, closing its leaves; a faculty common to an abundance of other plants, and very wonderful, having their constant periodical vigila; defigned by the fupreme Author of nature, as is thought, for the great end of fœcundation \*. With the root, and the pinebark, the poor Swedes are faid to have kept themselves alive in the want of other food in times of great dearth †. The distilled water of the flowers and leaves is an antient and approved remedy in fevers, and for all kinds of inflammations. It is also of antient use as a cosmetic, clearing the skin of pimples, and other deformities, caused by hear, giving it an agreeable softness. A bath made of the leaves, gives composure and rest to persons under fatigues from long and unseasonable watchings, by only washing the feet at going to bed, when it is warm. Made into a fyrup, it promotes sleep. The Turks make a liquor of it, of which they are very fond ‡.

167. The great yellow Water-Lily (g) is plentiful in the fame lakes, and in many flow running waters; in the rivulets of Pont and

172. Adders-tongue (r). On the borders of a wood by a footway below Honeyclugh-crag, on the east fide of a streamlet, near Chesterwood, in great abundance, on a dry bank, used for meadow. I never met with it in any other place with us. The root is orbiculated at the crown, with cylindric bulbous fibres, an inch and a half or two inches long, equally and uniformly extending every way in the ground, three or four inches deep. It fends forth a fingle ovated leaf, without a nerve, thick and fucculent, of a yellowish-green. The stalk is from three to near five inches high. The tongue is flender and mucronated, for the most part fimple, but fometimes bifid, and not unfrequently trifid. The fructifications are closely arranged in a double feries to the middle of it, with an elegant kind of ferrature at the edges. It flowers in May and June. It is used with great commendations for green wounds. Made into an ointment with Dwarf-Elder, it is an effectual and never-failing remedy for cattle bitten by the adder, and other pernicious reptiles.

173. Moonwort (s). In dry hilly pastures. On both sides of the Roman Wall at Tower-tay, near Wall-wick. In a pasture near the

below the water-fall; also about the rocks by the spring at Long-Crag, near Watling street. The younger plants are disposed on the ground in the form of a star.

175. The flowering Stone-Fern (w) is plentiful among the rocks under the Roman wall, on the west-side of Shewing-sheels. It is also among the rocks by Crag-lake, towards the west end, in great abundance. It grows in tusts. The root is composed of long, black, capillary fibres. The stalks are naked for four or sive inches; smooth, and slender. The foliola are of a lively green, elegantly cut; part like those of curled parsley, and part narrow and reslex at the edges, on which are the fructistications, perfected in August and September, of a beautiful orange-yellow.

176. Hind's-Tongue (x) is fearce with us. I have observed it to grow sparingly among the rocks by a small cataract, or waterfall,

under the freestone-quarry on the west side of Hall-barns, near Simonburn. It is also in the wood by the slate-quarry at Blake-law, opposite to Low Moralee, near Wark, in Tynedale. The root is sibrous, creeping, and divaricated, sending forth new plants at distances. The stalk is naked for about three or four inches, of a blackish-green, smooth and glossy. The pinna is cordiform, broad at the bottom, and shorter all the way up; of a pale, but beautiful green, keeping its colour in drying. It is often gathered and sold to the shops for the Trichomanes by the common herbarists, with which it is so nearly allied in virtue, that it is adjudged by a scarned author at Paris to be one of the chief pectorals, and is therefore admitted there, and with us, among the capillaries, but not by the Germans\*.

180. White Maiden-bair, Wall-rue, or Tent-wort (c), is not common. It is sparingly on both sides of the bridge over the Tyne at

Corbridge. It is also sparingly in the fiffures of the church-wall of St. Peter, in Bywell. There is a plant of it in a fiffure of the chancel-wall of the church at Simonburn, on the north fide. It was more frequent before many of the old towers and other antient castellated buildings were pulled down. It was in great plenty, and larger than common, in the joints and crevices of the old ruin of Simonburn-castle, before it was taken down, and an artificial one raifed in its room, for an object of pleasure, by its owner, Sir Lancelot Allgood, of Nunwick, Knight. Some of the plants that were sheltered within the bollows from the winds, were four, and others near five, inches high, fustained by no other nourishment than the mortar, a mixture of lime and fand, and fuch falts as might be derived from the walls, mellowed by age, and parting freely. The fructifications are on the backpart of the foliola, perfected in September, of a coal-black. It is one of the five capillaries, and is not unfrequently used as a fuccedaneum to the true maiden-hair. Its chief use is as a pectoral, in the form of tea\*. There are some who advise it for the scurvy †. It fometimes enters into emetic draughts ‡.

181. Polypody (d) is frequent at the roots of trees and about rocks in damp mountainous woods, and old fhadowy stonewalls,

whitish-

whitish-green. The branches are thin set, the shortest about an inch long, the middle ones larger, producing but sew pinnules, and sparingly, not more than nine. The largest have three servatures, the rest only one. The fructissications are round, about sive together.

There is a variety of it in the fiffures of the moister rocks of a more firm texture (1), owing chiefly to its situation.

188. The least Stone-Fern (m) is on the east side of a large rock in the brook opposite to Tecket, sparingly. It is from an inch to two inches long, rarely more. The folioles are shorter and less than those of the Trichomanes. I have observed it in a sissure of the same rock with the sasson-yellow Bysus, and the small fringed Lichen, rising through the middle of them. It dies down to the root on the approach of winter, commonly before October. Its smallness often makes it overlooked and unobserved.

189. The fine cut Stone-Fern, with slender brittle stalks (n), is not unfrequent about alpine-rocks. I have observed it among some of those at Tecket; also at Little Waneyhouse-crag, near Swethope-lake. The stalks, in general, are half a foot high. The branches are sparingly disposed. The pinnules are lobated and serrated.

The largest lobes only are cut to the nerve. When the lobes are rounder, broader, and not so deeply cut, it makes a variety different from the next to be described. The groups of fructifications are larger, and in old plants entirely cover the back part of the lobes.

- 190. The flender Stone-Fern, with crefted folioles (o), is frequent in the clefts of alpine-rocks. I have observed it in the fissures of Tecket-rocks, and other places. It very much resembles the former. It differs from it by its narrow pinnules, and bisid acute ferratures, ending in spinules, like the fmall crested Fern, and cut to the very nerve; also by the smaller number of fructifications on the back of the folioles, which never cover them entirely.
- 191. The *small branched Female-Fern* (p), is not uncommon in woods. It is a foot high. The branches are in pairs on the stalk, and gradually shorter. These also are branched, and have distinct pinnules, firm, close, and long, marked with parallel lines. The fructifications are in groups, and yellow.
- 192. The great branched Male-Fern, with crefted pinnules (q), a beautiful fern, is not common. I have observed it among the

damp

damp rocks by the brook below Tecket, and under the trees on the banks of North Tyne, on the fouth fide of the oftium of Wark's-burn, sparingly. The branches are in pairs on the stalk, and gradually shorter, like those of the common Male-fern. They produce others in pairs after the same manner. They have pinnules, rather broad than winged, sparingly disposed, with deep acute ferratures, each denticle ending in a herbaceous spinnule. The whole plant is firm, and of a lively glossy green.

193. Great rough Spleen-wort (r) is not unfrequent. It is on the shadowy banks of North Tyne, on the south side of the ostium of Wark's-burn, where there are a great variety of ferns. The stalk is chaffy. Many of the pinnules are of an equal breadth. They have remarkable triangular soliaceous appendages at the base; and are acutely crenulated at the edges, the denticles ending in spinules. The fructifications are in round dots on the back part of the margin, about twelve or more, in a double series. Its whole form is more rough and sirm than any of the other ferns, and easily distinguished from them at sirst sight by its chaffy complection, of a reddish-brown.

194. The prickly auriculate Male-Fern (s) is plentiful among the damp shadowy rocks by the brook below Tecket; also among those

those below the small cataract in Honeyclugh, near Chesterwood. The stalk is chassy. The branches are gradually shorter all the way up. Two, and sometimes four, pair of the pinnules are distinct and auriculate, but many of them run into one great segment. The folioles are prickly at the edges, and lanceolated at the ends; of a lively glossy green on the upper part, and rough underneath. The fructifications are on the under disk, in orbiculated or round dots, in a double series, in number sourteen, perfected in the latter end of autumn. It makes very different appearances according to its different stages of growth, and situation. Seminal plants, about moist dripping rocks, assume the form of the sine-cut Stone-fern, and continue so for about a year under culture, with tumid conspicuous veins, and then change to the state described.

195. The great, prickly, auriculate Male-Fern (t), a variety of the former, is on the wood-bank, under the steep rocks, below Tecket. It differs from it by its size, and the number of distinct pinnules, even to ten pair, which are auriculate. In other respects it is like it \*.

\* Olim C. BAUHINUS suam aculeatam majorem multis modis ludere deprehendit, ut CL. HALLER. observatum, l. c.

For the first discovery of the fructifications of ferns in England, we are indebted to a curious and fagacious naturalist of Bristol, Dr. William Cole, who gave an account of it to the secretary of the Royal Society, Dr. Robert Hook, Sept. 30th 1669. The learned Swammerdam has an epistolary differtation on the seed of the male-fern in his Biblia Natura, and at the end of it a curious engraving, representing the seed-vessels, their mechanism, and the seed as viewed by a good magnisher.

Mosses and Submarines are numerous. I shall only take notice of such as are of oeconomical use, or curious, according to my proposed plan.

1. Long, implicated Tree-Moss, or Usnea of the shops (u). On the steep perpendicular precipices at great Waneyhouse-crag, in great abundance. It is five or fix inches long. The fructifications are in the form of scutella, or dishes, on the sides and at the extremities of the more robust and rigid plants. It was a principal ingredient in the samous perfumed powder, called Pulvis Cyprius; formerly of so great account at Montpelier in France, as to form a considerable article of trade\*. The Laplanders use it for their feet after much statigue in walking. It is said to be a rare plant in England †. It varies in its form according to its age, being very

<sup>(</sup>u) Muscus arboreus, Usnea Officinarum. C. B. Pin. p. 361. Raj. Hist. i. p. 114. Syn. iii. p. 64. n. 1, &c. Dal. Pharm. p. 59. <sup>\*</sup> I. B. ii. where is the whole process of making it.

bushy and tangled in its younger state. In its older one it is more open and less implicated, as it grows in length and thickness. Those that bear the fructifications are robust, with dichotomous branches, fome with finer, and others with more rigid points, or fibrils. These Micheli has figured four different times as four different plants. One of these, which is the first he mentions, he calls the knotty Ufnea (w). The knots are only the fructifications, which before they expand into the form of dishes, are orbicular, and look like knots. The fructifications of the alpine crested coralline Moss are formed after the same manner. He has drawn it more after nature than Dillenius. The fecond is that I have referred to among the Synonyms, used by the judicious Haller. It has longer and finer points. Dillenius acquaints us he never observed it in all his searches \*. The third is with rigid (x), and the fourth with fmall (y), fibrils at the ends. It is in all these forms on the face of the same steep and lofty precipices. It is one and the fame plant under all these appearances in its state of fructification. An over-fondness for being the author of the discovery of new and unknown plants, natural to the most ingenious men, stimulated by a generous ardour for the enlargement of knowledge, led the learned and curious Micheli into this mistake; and a want of opportunity for observation, made it not mended by others.

<sup>(</sup>w) Lichen nodosus, cinereus, longissimus, receptaculis slorum resuscentibus. Michel. Ord. v. t. 39. f. 1.

<sup>(</sup>y) Lichen ex cinereo candicans, longissimus, surculis rigidioribus, receptaculis slorum resuscentibus. Ibid. t. 39. f. 4.

- 2. Black Mane-Ufnea, or Rock-Hair (z). On the perpendicular steep of great Waneyhouse-crag, with the former. On Raven's-hugh-crag, near Simonburn; also on the precipices under the Roman wall by Crag-lake, plentifully; in pendulous tufts, from four to seven or eight inches long, of a greenish-black, and sometimes entirely black.
- 3. Black Wool-Usnea (a). On a large rock above the water-fall at Tecket, on the north-west side. On the branches of the Erica, or common heath, projecting over the tops of the rocks at Long-Crag, by Watling-street, near Swinburn-castle. It has very much the appearance of black wool, spreading, and variously implicated, soft in winter and in the spring, but afterwards dry and rigid.
- 4. Stringy spreading Usnea (b). On alpine rocks, and the trunks of old trees. On a large rock on the south-east side of the brook below Tecket-water-fall, plentifully.
- (z) Lichen capillaceus longissimus s. Muscus arboreus nigricans, Usnea Officinarum. Michel. Ord. v. n. 7. p. 77. Hall. Helv. p. 70. Muscus arboreus capillaceus longissimus niger. Scheuchz. - fouth fide of the brook opposite to Tecket, by the path to Upperton. On the rocks by Crag-lake. It is a very small elegant plant, in tufts, half an inch long, divaricated and branched, the two last branches ending in two short horns, of a glossy black.
- 6. Brown, prickly, folid, Coralline Moss (d). On the rocks by Crag-lake, in tusts. The stalks are an inch long, compressed, and branched; the branches ending in very minute spinnules, without any conspicuous receptacules for the fructifications: of ablackish-brown, or chesnut colour.
- 7. Crisp, warty, solid, coralline Moss (e). On the rocks under the Roman wall by Shewing-sheels, and by Crag-lake, at the west end, plentifully. It grows in broad tusts, sometimes taking up a space of half a foot, or more, nourished by a thin coat of earth,

formed of decayed putrid moss. The stalks are from an inch to an inch and a half long, and branched, with short sibrils, and warty excrescences of a greyish-white, as if powdered. The fructifications are on the sides of the more rigid sibrils, in the form of very small black tubercles, sometimes smooth, and sometimes uneven, appearing through a magnifier as if two or three were joined together. It is a scarce plant. Dillenius refers us to the Welch mountains, and the transmarine Alps, for it.

- 8. Cypress-like, solid, coralline Moss (f). On the rocks at Long-Crag, by Watling-street; also on the rocks by Tecket-water-fall, plentifully. It is from an inch and a half to two inches high. The younger plants are thick fet with folioles, the older ones with few, of a light brown, with a tinge of bright grey, in their recent state, and glossy. The fructifications are at the top of the more robust plants, on short rigid sibrils, in the form of orbicular or round tubercles, first of a light glossy brown, and afterwards black. Some of both colours are on the same plant in March. It is accounted a scarce plant, and not very plentiful, even at Snowden.
- 9. Crefted, fine-leaved, folid, coralline Moss (g). In a remarkable fiffure, or finus, on the top of great Waneyhouse-crag, called the Bier, plentifully. On the east side, and near the bottom, of a large shadowy rock on the south side of the brook below Tecket-

water-fall, near the top of the bank. It has only a thin coat of earth, formed of rotten moss, to sustain it. The stalks are from an inch to an inch and a half long and branched. The folioles are fine, close, and thick set, down to the very base of the younger plants, of a grey colour, with a cast of sea-green, and sometimes with a blush of red. The fructissications are on the tops of the branches of the more robust and aged ones. They are first roundish, and afterwards expand to a flat circular form, a quarter of an inch in diameter, of a beautiful black, with a purplish cast; in their recent state resembling the nap of velvet. Above them is a crest of fine short spinnules. It is a scarce plant. Dillenius refers us to the Welch mountains for it. It is in its greatest beauty in the latter end of September.

ro. The prickly, distorted, tubulous, horned Moss, with foliaceous excrescences (h), is not unfrequent on dry barren heaths, and on old walls topped with earth. It is on an old wall on the fouth side of the military road, a quarter of a mile west from Carraw, plentifully. It is from two to three or four inches high, and branched, in the form of a little bush, dichotomus, distorted, rigid and prickly. The fructifications are small and orbicular, at the top of the incurvated fibrils, first of a sless-colour, and afterwards brown; perfected in autumn. It varies in its size and shape, according to its age and situation. On shadowy heaths and walls it is robust, and frequently compressed. In a

<sup>(</sup>b) Lichen coralloides, tubulosus, major, montanus, e cinereo-viridi resuscens, caulibus recurvis, nonnihil foliosis, inordinate dispositis, receptaculis slorum crassioribus resuscentibus. more exposed situation, on dry walls, and naked rocks, it is meager and slender, but in both these states it is covered with a scabrous crust. It sometimes, indeed, loses its coat by being weather-beaten, or by age, and then it is sometimes taken for a different species.

- about dry alpine rocks, and on old walls, topped with earth. It is plentiful on the fame wall with the former. It is also upon Tecket-rocks. It is in the form of a little bush, from an inch to three inches high, usually of a dark grey or brown. The branches are glabrous, slender and rigid, ending in restex sharp sibrils.
  - 12. The foft, grey, tubulous, horned Moss (k), is not uncommon in the openings of woods, and barren shady places. I have observed it under the bushes by the road between Broadpool-common and Thorough-gates, near Simonburn, in autumn. It is three or four inches high, of a whitish-grey, sparingly set with branches and foliaceous excrescences. The fructissications are on the tips, small and orbicular, of a reddish-brown.

lington, near Wark, in Tynedale, plentifully. The stalks of the young plants are round, of a bright white, tipt with brown. Those of the old ones are compressed, and entirely brown; which are the distinctions between it and the former.

- 15. Great, foft, open, coralline Moss (n). On moist heaths. On Broadpool-common by Ravenshugh-crag, at the roots of the Ericæ, plentifully. It is three or four inches high, perforated at the divarications of the branches, and also at the ends, with spinnules elegantly disposed in the form of a star.
- 16. Small, foft, open, coralline Moss (o). With the former, frequent. It is from an inch to three inches high, with very short branches at the top, perforated like the former. At the bottom and on the lower part are small folioles, of a pale green above, and white underneath, sparingly crenated. The upper part is thick set with foliaceous excrescences. The fructifications are on the tips of the sibrils or branches of the more robust plants, small and orbicular, of a reddish-brown, perfected in September.
- (n) Lichenoides tubulosum, cauliculis mollioribus & crassioribus majus. Raj. Syn. iii. p. 67. n. 20. Coralloides persoratum majus, molle & crassium. Dill. Hist. Musc. p. 98. t. 15. f. 21.
- (o) Lichen coralloides tubulosus, albidus, minor et mollior, caulibus crassioribus, minus ramosis, receptaculis slorum perexiguis, resuscentibus. Michel. Ord. vi. p. 79. n. 7. - 17. There is a VARIETY of it on Tecket-rocks a little more than an inch long, thick fet with foliaceous excrescences, in the form of a flag's-horn (p).
- 18. There is another VARIETY among other mosses in the finus or large aperture, called the Bier, on the top of great Waneyhouse-crag, near Swethope-lake, with slender stalks, two or three inches high, divided into two staight, upright forks, or tubules (q).
- 19. There is a third VARIETY in the shadowy clefts of Raven's-bugh-crag, and of the precipices by Crag-lake, with short, thick, cylindric stalks, an inch and half long, sparingly set towards the top with short, slender seta, with numerous minute crenated folioles, larger on the lower part and at the bottom, of a pleasant seagreen above, and silvery underneath, shrivelling up in drying (r). It is in its greatest beauty in September, when the fructifications are perfected, of a reddish-brown, and orbicular, on the obtuse ends of the stalks. It is very soft and tender, and loves to be sheltered from cold and rain by other plants, or the projections of the rocks, and therefore is commonly found growing in broad tusts in places not exposed, in some cavernous part or warm recess, towards the bottom.

- (r) Coralloides foliolis crenatis læte virentibus superne, subtus argenteis, caule molli cy-Jindrico, leviter setaceo.

- 20. Small, branched Moss, with scarlet Heads (s). On moist rocks, and upon heaths. On the rocks of Tecket. On Broadpool-common by Raven's-hugh-crag. On Calleley-hill, in great abundance. The stalk is an inch high, sparingly branched. The heads, or fructifications, rise in February, of a beautiful scarlet.
- 21. Proliferous, Cup-Moss, with scarlet tubercles (t). On dry alpine rocks. On the rocks in Rotheley-park, near Wallington. The tubule or stalk is an inch high or more, of a greenish-grey, and sometimes of a light-grey. The fructifications are elegantly disposed round the edges of the cup, in the form of tubercles, and in its proliferous state often entirely efface it. They are of a bright scarlet. Insufed in lye, they are faid to strike a purple, fair and durable. It appears in October, and holds its beauty all the winter, till late in the spring. The scarlet turns to a deep purple in drying.

22. Thigh-

four or more in a group, from two to three inches high, with laciniated folioles at the base, and on the lower part; of a lively sea-green above, and silvery underneath. Some of the younger plants are naked, in sigure like a horn, and often mistaken for a species of the horned moss. The more robust and aged ones are branched and proliferous. It is elegantly drawn in its different stages of growth and variations by Dillenius and Micheli\*.

- 25. Branched Cornu-copia Cup-Moss (x). About the decayed flumps of trees in woods, and moist alpine rocks, frequent. It is two inches high, with crenated folioles at the base, of a light grey. The fructifications appear in the spring on the points of the serratures of the cup, in the form of small round tubercules.
- 26. The clumfy indented Cup-Moss (y) is frequent among the erical under Raven's-hugh-crag, in winter and in the spring. The stalk

or tubule is an inch and a half long, with laciniated folioles at the bottom, and on the lower part. It is first erect, and afterwards incurvated, of the thickness of a common writing-quill, simple, and some with one or two branches, slender towards the base, and more robust upwards, with soliaceous excrescences, of a dull grey, with a greenish cast.

- 27. The tall, flender, brown, indented, Cup-Moss (z), is not unfrequent on the rocks by Crag-lake, many of them together in a group. It is two inches high, flender, and of a bright flining brown. The denticles of the ferratures of the cup turn up, and become pedicles to fustain the tubercles or fructifications, which are of a reddish-brown and entirely efface it.
- 28. There is a VARIETY of it at the roots of the erice about the rocks at Raven's-hugh-crag, with incurvated spinnules or branches, rising towards the middle of the stalks. The cups are oblong, deep, and moderately lacinized at the edges, somewhat resembling the sockets of a candlestick; as does the whole plant a branched one, in miniature (a).
- (z) Lichen pyxidatus & corniculatus ramosus alpinus e susco-cinereus, pyxidulis crenatis. Michel. p. 81. Ord. vii. n. 9. t. 41. f. 5. nomen, non autem Icon, Cl. Hall. judice, loco infra cit. sub. n. 30. t. 41. f. 5. Lichen pyxidatus, ramosus, acetabulis simbriatis. Ejust. ib. n. 10. Tourn. Inst. p. 545. Vaill. Bot. Paris. - (a) Coralloides montanum elatius & ramosius, e susco glabro, calycibus oblongis leviter laciniatis.

This species is always of a smooth shining complection, which is a distinction reckoned peculiar to it.

- 29. The finall, rattle-leaved Trumpet-Cup-Moss (b), is frequent in dry barren places upon heaths, also on old walls topped with earth under trees, and about rocks. It is an elegant little plant, of a trumpet-like form. The cups change to flender filiform pedicles to fustain the fructifications, which are in the shape of minute scarlet tubercles. It is very rare to find it in this state. I met with it on the rocks by Crag-lake.
- 30. The flender indented Cup-Moss (c) is not unfrequent with the former, and the Chalice-Moss (d). It is sometimes proliferous to the third degree, in which state it is very beautiful.

The

33. Fine green Lichen, or Liverwort with black warts (b). On the rocks under the Roman wall by Crag-lake, sparingly. The digitated lobes of the older plants are large, concave, or turned inwards at the edges. They are of a lively glossy sea-green on the upper part, whitish at the edges underneath, and the rest of a dark brown. The fructifications are in the form of small warts or tubercles, of a coal-black. It does not hold its colour in drying, but the whole plant with the fructifications, turn brown. From one of these it is sometimes described by authors, for want of an opportunity of seeing it in its recent state. It is a very uncommon plant. Dillenius observed it in the woods about Gissa, but assures us that he never met with it any where else.

34. Smooth, pitted, Endive-like Lichen or Liverwort (i). On dry rocks, and on the ground. On a large millstone-rock above Tecket-

water-fall, on the north-west side; also on another large rock on the north-side, near the top of the bank, plentifully. It covers almost the whole face of the first rock eastward, and is sustained by a little thin spongy earth, formed of decayed putrid moss. The leaves are erect, concave, or turned inwards at the edges, and laciniated, brown underneath, and of a silvery glossy white above, with a cast of sea-green in the younger plants. The fructifications are on the older ones, in the form of minute brown tubercles, which on a silvery ground form a beautiful variegation. It is not in the Flora Angelica. We are referred to the transmarine Alps for it by Dillenius.

35. Purple, tinctorial Lichen or Liverwort, with black scutelle or dishes (k). On the steep rocks under the Roman wall by Craglake, towards the west end, plentifully; also on a steep rock at Raven's-hugh crag. The folioles are implicated, elegantly laciniated, and sometimes bissid at the ends, about an inch long, of a dusky purple colour, and blackish when dry, thick set with long, rigid, black hairs, in one or two lines underneath, conspicuous at, but not growing on, the edges. The scutelle or fructifications are orbicular, and turn inwards. The common people in the mountainous parts of Wales, Derbyshire, and Scotland, use it in dying purple, prepared by powdering and urine. The Welch

<sup>(</sup>k) Lichen Pulmonarius, tinctorius, foliis eleganter, & tenuiter divisis, inserne nigricantibus, & cirrhosis, superne purpureis, & lacunatis, receptaculis slorum concoloribus. Michel. with:

with the two common species, with reddish-brown (o) and with large black scutellæ (p). It is usually in broad orbicular groups, moderately thick, adhering close to the rocks; but in its older state, easily raised in large plates and entire with a knife; of a whitish-grey, or silvery colour. The scutellæ or fructifications are numerous; first white, afterwards of a light red, and at length of a deep purplish-red and glossy, with a white circle round the edges, sometimes crenated, and sometimes not. It is exceedingly beautiful in its state of fructification, elegantly variegating large rocks at the two former places. It is accounted a scarce plant. Dillenius refers us to the Welch alpine rocks for it. It is not in the Flora Angelica.

- 38. Grey, tinctorial, crustaceous Lichen, or Stone-Moss, with large yellow dishes (q). On the rocks at the two Waneyhouse-crags; also on those of Raven's-hugh and Tecket, plentifully. It is thick, leprous, and spreading, of a rugose granular surface, and often mealy, of a silvery grey colour. The orbicular scutelle or fructifications are large, moderately concave, of a fair pale yellow,
- (o) Lichen crustaceus arboribus adnascens ex cinereo-albicans, receptaculis storum crebris subsuscialis dibo crenato cinctis. Michel. Ord. xxxiv. n. 29. p. 97. with a white circle round the edges. Our common people on the wastes, who call it Cork, dye a fine red with it. They prepare it by drying, powdering, and steeping it in urine, as the French do the Pérèlle. The Welch call it Caddlod and Ken Gwin, and use it also in dying red, prepared after the same manner. It is a beautiful plant in its state of fructification. It was thought peculiar to Wales, till Dr. Richardson observed it on the alpine Yorkshire rocks. In the Flora Angelica, it is called the Welch-Liverwort.

- 39. Crayfish-eye-like, tinctorial, crustaceous Lichen, or Stone-Moss (r). On moor-stones, of the fine rag-kind, about Crag-sheels, and Black-bow-burn, i. e. the Black-bill-burn, near Wark, in Tynedale. The Stones are so remarkably white with it, that they may be discerned at a considerable distance, in all seasons of the year. The dishes or fructifications are of the same colour. The limb is convex, yellow, and slessly on being cut through. It is the Pérille d'Auvergne, or Orseille de Terre, of the French, in the province of Auvergne, for striking a purple or red, known to them before the discovery of the Orchel, an extraneous lichen from the rocks of the Archipelago, the Canary-islands, Cape-Verde, &c. to which it is inferior in quality, but in more common use. They prepare it with urine and lime. The Orchel is prepared with urine and potash. It is a scarce plant. It is not in the Flora Angelica.
- 40. Hard, white, tinctorial, crustaceous Lichen, or Stone-Moss, with black tubercles (s). On alpine rocks, frequent. On the rocks at

Raven's-

Raven's-hugh-crag. On the rocks by Crag-lake. It is moderately thick, granular, and of a cracked furface, fometimes mealy. The tubercles or fructifications are of a convex form, coal-black, appearing in January. 'The Welch use it in dying scarlet. They prepare it by powdering, and infusing it three weeks in urine. They prefer it to what they call Kenkerig.

- 41. Yellow, Map-like, crustaceous Lichen, or Stone-Moss (t). On the whinstone-rocks by Crag-lake, at the south-west end, close by the Roman wall, plentifully. The fructifications are in the form of black Areolæ on a yellow ground, resembling the lines of a map, making an elegant and beautiful variegation. It is a scarce plant. Dillenius refers us to the Welch mountains, and to the transmarine alps, for it.
- 42. Greenish-white, farinaceous Moss, with fungus-like Tubercles (u). On mountainous mosses, also on the tops of large rocks, in a

moist turf-soil, with other mosses. On the top of great Waney-house-crag. On a large rock on the shadowy bank below Tecket-water-fall, on the south side. On the heath-grounds by Halypike-lake, plentifully. It lies on the moss-earth, and sometimes on the sphagnum with restex solioles, in the form of a mouldiness. The tubercles or fructifications are of a beautiful sless-colour, and cut through like a fungus. It is an elegant little plant. It was never known to grow in England, till the late Dr. Richardson, of Byerley, in Yorkshire, found it on the alpine mosses in that county.

43. Creeping Wolf's-Claw-Moss, or Club-Moss, with alternate folioles and branches (v), is not unfrequent on alpine heaths, and shadowy rocks. It is among the rocks by Crag-lake. It is also on the heath on the fouth fide of the Roman station at House-steeds, by a small rill, near the military-road. It is a very rambling plant. It is fixed down to the ground by small fibres rising from the under side of the branches. The folioles of the younger plants are of a lively green, those of the older ones are yellowish, at the ends of the branches of which are short juliferous spikes, of a pale yellow or straw-colour. Under the scales of these are the fructifications in cordated capsules, in the form of a yellow powder; perfected in August. It is used for cutaneous inflammations, sis-

fures and chaps of the skin, the pain and anguish of which it relieves by its remarkable emollient and anodyne powers \*.

- 44. Creeping Cypress-Moss, or Heath-Moss (w), is frequent on Cheviot, in places somewhat wet. It creeps on the ground, like the former, and is branched in a dichotomous manner, sometimes with five, six, or seven short ramifications, two inches long. The younger plants are of a lively green. The older ones are more upright, and yellowish. The short juliferous spikes are of a straw-colour. The fructifications are between the scales in reniform bilocular capsules, like a small yellow powder, perfected in September.
- 45. Upright Fir-Moss (x) is plentiful among the moist rocks under the Roman wall, on the west side of Shewing-sheels; also among the

the rocks under the fame wall by Crag-lake, towards the west end, where it is frequently six or seven inches high. The root consists of small capillary sibres, from which rise one, and sometimes two or three stalks, with branches in a dichotomous manner, sirst two, then other two, and sometimes two more, according to its age and strength. The folioles are oblong, narrow and pointed, a little convex on one side, and concave on the other, more close and thick set upwards than at the bottom of the stalks and branches, especially at the ends. The young plants are green; the older ones yellowish. The fructifications are in the alæ of the folioles in yellow reniform capsules, like a yellow powder, perfected in August and September. It is a beautiful plant in its state of fructification, the folioles and capsules being then of a bright gold-yellow. It is an emetic and cathartic, and is used as such by some people.

46. Trailing Hypnum, with waved fins (y), is among the rocks under the Roman wall by Crag-lake; also among those at little Waneyhouse-crag, sparingly. It is of a compressed shape and creeping, sometimes simple, and sometimes branched, two or three inches long, of a yellowish-green, and glossy. The fructistications rise in April from the alæ of the leaves, on capillary pedicles of a fine red. The capsules are oblong, and of a straw-co-lour with calyptra. At the base of the pedicle is a squamose matter, or involucrum, called by Dillenius, Perichætium, which is

the great characteristic of the Hypna. It is a beautiful plant, and retains its colour a long time in drying.

- 47. Hoary Hypnum-like Mountain Bryum, with the fructifications in orbicular capfules on the sides of the branches (z), is common on alpine rocks in large tufts. It is on Tecket-rocks; also on those by Craglake, and the two Waneyhouse-crags.
- 48. Long, transparent Mother of Thime-leaved Bryum, with Sharp stooping heads (a), is on the shady dripping rocks on the edge of the brook below Tecket, plentifully. It is accounted a scarce plant. Dillenius refers us to the Welch mountains, and to the transferance Alps for it.
- 49. Branched Polytricum, bearing heads from its tops (b), is frequent on Broadpool-common, by Raven's-hugh-crag. It is a fcarce plant. We are referred to Snowden for it by Dillenius.
- 50. Small Stone-Licken, or Liverwort, with crenated folioles (c), is frequent on Tecket-rocks.
- (z) Bryum hypnoides, capitulis plurimis erectis, lanuginosum. Raj. Syn. iii. p. 97. n. 28; Hall, Helv. p. 102. t. 3. f. 4. Muscus trichoides lanuginosus alpinus. Petiv. n. 85. I observed it on a large rock on the edge of the brook opposite to Tecket, on the south side, sparingly. It is disposed in an orbicular form, from the size of a shilling to that of a crown-piece, of a deep purple at the base, and of a bright yellowish-green at the edges, elegantly laciniated. The fructifications are globuliferous, on capillary pedicles about an inch long, mature in September. It is a beautiful plant.

For the first discovery of the flowers and seeds of mosses, we are indebted to Micheli.

Next of Submarines.

three inches touth ander

- 1. White Sea-Coralline (e). On the shore near Dunstonbrough-castle, on the north side, plentifully in spring and autumn, on shells and other marine bodies, in tusts. It is commended as a vermisure, given from ten grains to two scruples in a dose.
- 2. Capillaceous, dichotomous, purple fucus, with multifid and yellow extremities, and white tophaceous hairy cases on the bottom and part of the upper branches (f). With the former frequent. It is four or five

inches long, very much branched, in a dichotomous manner, and divided at the points, fome bifid, or trifid, and others multifid, of the thickness of a strong horse-hair, with cases regularly bristled or set with short hairs. It is of a deep purple, except at the ends, which are of a pale yellow. It is also frequent without the bristled incrustation.

- 3. Small fearlet Fucus, with a porous incrustation on the branches (g). On the same shore, sparingly. It is three inches long, moderately branched, of a bright scarlet. The incrustation is white, porous, and in parts hairy, spangled with glittering testaceous corpuscles. It is also frequent without the incrustation.
- 4. Small fearlet and white fucus (b). On the fame shore, and other places on the coast, sparingly. It is membranaceous and divaricated, two or three inches long, of a beautiful scarlet and white. The scarlet holds its colour in drying. The white turns to a straw-colour.
- 5. Purple, membranaceous, esculent Fucus (i). On the shores of Cresswell, Dunstonbrough, and Berwick, plentifully. Our sishermen call it Dulse. In Scotland it is called Dils, and in Ireland, Dulesh.
- (g) Fucus membranaceus ceranoides varie dissectus. Raj. Syn. iii. p. 44. Alga minor suave-rubens varie divisa. Mart. Dec. p. 32. t. 32. Fucus membranaceus ramosissimus, ramulis linearibus. Linn. Flo. Suec. n. 1012.

Of Lythophita or stony submarines, I have observed only these two.

- 1. A Sea-Mushrome, in the form of the tuberculose headed Ly-coperdon, with a kind of an oblong thick pedicle of a glossy white, like an enamel, with irregular blotches of a shining vermilion-red. Broken, it shews a laminated texture, and a Congeries of Tubuli vermiculares from top to bottom (k).
- 2. A fessile, echinated Sea-Mushrome, of a glossy white, with the same Tubuli vermiculares within (1). I had both these from the sea-strand at Ross-links, near Belford. They seem to be the production of some sea-cavern.

From the Mosses and Submarines, proceed we to the Mushromes. They are not less numerous. I shall only mention those that are of highest rank at table, and such as deserve notice for their configuration and beauty.

- 1. White esculent Mushrome with red gills and a convex crown, with divaricated prominent ridges and furrows, forming a kind of reticular work (m). I met with it on the common between Goston and Long Lee, near Wark, in Tynedale. I took the figure off with the
- (k) Coralloides fungiforme maritimum lamellatum pileo albo-rubente glabro tuberculoso, pediculo oblongo brevi, tubulis vermicularibus intra creberrimis.

- (m) Fungus camprestris superne albus, eleganter reticulari modo striatus, subtus lamellis pulchre rubris.

. . .

Thurston-clay. It is a beautiful variety of the common Champignon (n).

- 2. Large white esculent Mushrome, with a remarkable broad crown and long pedicle (o). In the bank of wood opposite to the rectoryden at Simonburn, not unfrequent in autumn. It is entirely white. It is accounted by the curious to be of a finer flavour than the Champignon\*.
- 3. Esculent, yellow, contorted Mushrome, or Chanterell (p). In shadowy pastures, and on the borders of woods. I have observed it under the trees at the west end of the rectory-den at Simonburn, and other places. It is of a pale yellow, and variously contorted, of an agreeable taste.

- 4. Purple esculent Mushrome, with white gills, and a white pedicle (q). In dry shady places. I observed it in a lane at the north end of a small village called Donkley-Wood, near Hordlee, upon North Tyne, near Bellingham, in September, plentifully. The pedicle is short, thick, and not bulbous. The head is a little depressed in the center, rough at the edges, and striated; sometimes of a beautiful purplishered, and sometimes of a rose-colour, with an admixture of white. The gills are thick, and thin set, with intermediate ruge, or a kind of half gills. They are white, and in their older state yellowish.
- 5. Esculent purple Mushrome, with a bulbous pedicle (r). In woods, in October and November, frequent. The pedicle on its first rising is a thick bulb, protected from the chilling night-dews and cold air by a close filky film, up to the very edges of its little head. It rises gradually higher; but in its highest state is very short and thick, carrying a head of a vast size, sometimes a foot

in diameter. The gills are of various orders, and moderately close set. It is entirely of a beautiful purple or violet colour, but of short duration, soon changing to a pale dull purple, or dusky yellow.

- 6. Small violet, or amethystine Mushrome (s). In the bank of wood opposite to the upper end of the rectory den at Simonburn, plentifully in September, among mosses, and on rotten sticks under the deciduous putrid leaves. It is of a firm texture. The stalk or pedicle is slender, tubulous, and thickest at the bottom. The head is convex, and small, for the length of the stalk, which is from an inch to two inches and a half. The gills are thick, and thin set. It is all over of a beautiful violet or amathystine colour, with a farina on the head, like what we see on sloes. The gills hold their colour a long time, but the head soon loses its bloom, changing to a pale bluish-grey.
- 7. Small blue and green Mushrome, with blue and rose-coloured gills (t). Among the moss on the trunks of old trees in thick woods. I observed it on the lower part of the moss trunk of a Scotch elm in the bank of wood by the brook below Tecket, plentifully, in October. The pedicle is an inch long, and slender, of a fine blue with an admixture of green. The head is hæmisphærical, and of

- (t) Fungus parvus elegans, Cantharidum colorem, splendorem & odorem æmulans, pileolo cum vertice lævi, reliqua parte pulchre striato, lamellis carneis, pediculo cylindrico sistuloso. Michel. Gen. Pl. p. 168. Striis dissert, colore alcedit. Fungus ex cæruleo viridis, lamellis cæruleo-roseis. Hall. Helv. p. 51. n. 83.

the fame colour, but changes by age to a pale whitish-grey. The gills are thick for its size, and not close set, of a bluish-rose-colour. It is pellucid, and held up by the stalk to the light, or lying fresh in its highest bloom on a table, has the beauty and suffre of a polished gem.

- 8. Small scarlet Mushrome, with yellow gills and a yellow pedicle (u). In the openings of woods. In an opening by a broad flexuous path towards the east end of the rectory-wood at Simonburn, frequent, in autumn, in small groups. The pedicle is an inch long, and thick, of a gold yellow. The gills are thick, moderately close set, and of the same colour. The head is convex, an inch and a half in diameter, of as bright a scarlet as can be imagined, on its sirst rising from under the herbage and fallen leaves; but vanishes by degrees to a reddish yellow, out of its shady situation, and, on being brought into a house, with the earth about it, languishes in a night's time to the same colour. It is sleshy and very brittle.
- 9. Scarlet Mushrome, with white fissile conic rays, white gills, and a white bulbous pedicle (v). Under fir-trees, not unfrequent. I observed it in confiderable plenty in a fir-grove at Brandon-white-house, by the rivulet of Bramish, in September. The bulb is thick and round, from which rises a pedicle of a bright white,

- (v) Fungus pileo coccinco radiis multifidis conicis albis varius, lamellis crebris albis, pediculo albo ad bafin globofo.

100

with a small round head, of a beautiful scarlet, glossy like sattin, with white sissile conic rays at distances, like those of the stellate Lycoperdon, forming an elegant variegation. The pedicle gradually rises higher, from an inch to three or four inches. The head also gradually expands, from an inch to three inches in diameter. The gills are sine, close set, and white. It is of a good sinell, and excells all others that I have seen for beauty. It holds its colour and gloss a long time in drying, under proper management.

10. Bloody Mushrome, with white warts, white gills, and a white bulbous pedicle (w), is frequent in meadows. The bulb is of a remarkable thickness. The pedicle rises gradually to an uncommon length, with an annular membrane, which soon vanishes, of a pure white. The head is first companisorm, and and afterwards flat, of a vast size, sometimes a foot in diameter; of a deep blood-red; variegated with warts, and striated at the edges. The gills are thin, numerous, and white. It is of a most ungrateful settld smell, and poisonous. We are informed by a learned foreigner, that it killed sive men with its virulent poison in Lithuania\*. It is much coveted by small slies, and for that reason is sometimes called the Flie-Mushrome.

<sup>\*</sup> Læsel. l. c.

bilicus in the center, and flesh-coloured gills and pediele (x). In alpine woods. In the rectory-wood at Simonburn, frequent, in August and September, under oak-trees. The pedicle is short, thick, and cylindric, an inch or an inch and a half long, of a pale red or slesh-colour. The head turns in at the edges, regularly deepening from the rim to the center, forming a concave or Umbilicus, with beautiful zones or circles round it, of a pale red, on a red-dish-brown ground, from two to four inches in diameter. The gills are close set, of a pale red or slesh-colour, and turn white by age. It is beautiful in its younger state, and keeps its colours a long time in drying.

12. Vifeid deep green Mushrome, with a white circle round the edges, and white gills, and a white anulated pedicle (y). In the bank of wood opposite to the upper end of the rectory-den at Simonburn, not unfrequent in September among mosses, and on rotten sticks, with the small violet or amethystine Mushrome. The pedicle is white, slender and tubulous, an inch and a half or two inches long, with an anular permanent membrane toward the top. The head is hemisphærical, of a deep green, with a circle of bright white at the edges, a little viscid and glossy, an inch in diameter. The gills are thick and not very close, of a bright white. It

<sup>(</sup>y) Fungus pileolo viscido, intense viridi, margine, lamellis, & stipite anulato albis.

holds its colour a long time in drying, except the gills, which turn brownish.

- 13. Gloffy, dark-grey, conic Mushrome, with white gills, and a white, bulbous, tall, anulated pedicle (z). In dry shady pastures, in autumn, not unfrequent. The pedicle is four inches long, with brown dots on a white ground, of a fine shape, tapering from the base to an anular permanent membrane, which in its younger state closes the mouth of the gills, like an operculum, and opens on its farther expansion, shewing their delicate whiteness. The head is of the shape of a large obtuse cone, of a dark grey, or ash-colour, of a filky lustre, which it retains in drying.
- 14. The great, white funnel-like Mushrome, with white gills, and a short, white, cylindric pedicle (a), is not uncommon in the openings, and on the borders, of alpine woods. I have observed it with the small scarlet and gold-yellow mushrome in the rectory-wood at Simonburn; also on the borders of Ramshow-wood, by the road-side, above the mill, near Wark, in Tynedale, in autumn. The pedicle is an inch long, and about as much in thickness. The head is at first reslex at the edges, which afterwards gradually rise upwards, and form a great hollow, like a funnel, sometimes five inches deep, and twelve inches over at the brims. The gills are very close, with intermediate shorter ones, or a kind of

flumps

stumps of fallen oaks. I never met with it on the stumps of any other trees. It is three quarters of an inch in diameter, and in its mature state covered with a white powder. The gills are fine and close. It is soft, pellucid, and nutant on the least motion. It is sometimes deformed, by growing in groups one over another.

- 18. Small, yellowish-white Auriculate-Mushrome, with gills of the same colour (f). On the trunks of old elms, by waters, in horizontal groups. It is frequent in the rectory-wood at Simonburn; also at the bottom of the adjoining wood at Tecket, in autumn, by the brook. It is sometimes disfigured, by its numbers growing over one another, horizontally.
- 19. There is a VARIETY of it on the same trees in autumn with large laciniated lobes (g), very beautiful.
  - 20. There is another Variety resembling a small Pieten (h).
- 21. Small, white, Auriculate-Mushrome, with white Gills (i). On the decayed stalks of plants in wood-bottoms, frequent. It is
- (f) Agaricum auriculæ, vel flabelli forma, superne subobscurum, inserne album, & lamel'a:um. Michel, Gen. Pl. p. 123. n. 4. t. 65. f. 1.

very fmall, thin, and nutant, of a bright white. The gills are fine, and close.

These Auriculate-mushromes, with gills, are all fixed to the trees, or decayed stalks of plants, horizontally, by a kind of pedicle, in some so small as to be almost imperceptible.

- 22. The great dufky yellow Mushrome, with Tubules underneath, and a tall, thick, bulbous pedicle (k), is frequent in woods, in autumn. On being cut, and the wound held up to the fun, the fluid gives all the colours, in its changes, of the rainbow. It is tinctorial, and gives a purple to linen \*. It is faid to be esculent, and not unfrequent at the Italian tables †. We are told by Linnaus that cows eat it, but that it makes their milk nauseous ‡.
- 23. The reddish-brown Mushrome, with yellow Tubules underneath, and a stender anulated pedicle (1), is less common. I observed it, in its mature state, at the upper end of the rectory-wood at Simon-

burn, under oak-trees in the middle of October. The tubules were covered for the whole length with the fructifications, in the form of a yellow powder. The exterior coat or film over their mouths was rotted off and perished, which shewed them to great advantage.

The tubules of these are capable of being separated from the crown, or the upper sleshy part.

- 24. Yellowish-white Mushrome with quadrangular tubules, and a thick pedicle (m). Under the fir-trees on the hill by the Roman wall at Tower-tay, near Walwick, frequent, in August and September. The root is succulent, and gradually rises to a thick pedicle, from an inch and a half to two or three inches long, and sometimes more. The head is from two to four inches in diameter. It is very soft and tender. The tubules or pores on the under part are square, terminated with dentated and orbicular protuberances. It is intirely of a yellowish-white, and turns to a gold yellow by age. Cut transversely, it shews the form of the tubules. It stains the singers on being touched, like the fassron clay-ochre, and disfuses a most ungrateful smell. It retains its form, yellow colour, and scent a long time in drying.
- 25. Ash-coloured, tessellated Mushrome, with quadrangular tubules or pores underneath (n). On alpine heaths. I met with it in Septem-
- (m) Polyporus Alni radicibus innascens, molli & crassa pulpa, pileolo desuper ex spadiceo fulvo, inferne luteo-viridi, pediculo brevi, supernæ pileoli parti concolore. Michel. Gen. ber on Bewick-common, in Glendale. I also met with it at High-Moralee, near Wark, in Tynedale. I took off the figure of its tessellated head with the Thurston-clay, which shews it to great exactness. The pedicle is short and thick. The head is convex, sive inches in diameter, with deep striæ, cracks, or clefts, resembling a tessellated or reticular work. The Alveoli, tubules, or pores underneath are square, and of an umbre-colour. Cut through transversely, their form is conspicuous.

The pores or tubules of this kind of mushromes cannot be separated from the crown or upper part.

- 26. Bright white esculent Mushrome, with long aculeated Spinnules underneath, and a tall pedicle (o). On the upper part of the bank of wood opposite to the rectory-den at Simonburn, in September, sparingly. It is intirely of a bright white. The pedicle is two or three inches long. The head is from two to three inches in diameter. It has a fine smooth skin, and changes to a yellowish-white in drying.
- 27. Pale yellow esculent Mushrome, with aculeated Spinnules underneath, and a short thick pedicle (p). In the same bank, in August, plentifully. The pedicle is short and thick, of a yellowish-white. The head is two or three inches in diameter, of a pale yellow, It grows both single, and in groups. The heads of the first are

Qq2

ufually

usually not deformed. Those of the latter mostly are disfigured by their numbers, multiform, and turned upwards with the spinules erect, in a crest-like manner. It holds its colour in drying.

28. Yellowifh-white, conic, cavernose Mushrome, or Morel (9). Under ash-trees, in a flood-soil, by waters, frequent, in April and May, after warm showers. In Claw-wood, on the banks of South-Tyne, near Allerwash. On the banks of North Tyne, near Chipchace; also on the banks of the brook at Simonburn. The pedicle is short, thick, wrinkled, tubulous, and white. The head is of a different form, according to its different stages of growth, situation, and flate of the feafon; fometimes like a tall pyramid, fwelling at the base; sometimes like a short, ventricose obtuse cone, and fometimes like a long acute one; always with numerous cells, larger or fmaller, according to its fize, forming a beautiful reticular work \*. Under the shade of ash and beach trees, on the edge of the brook opposite to the upper end of the rectory-den at Simonburn, in a rich fandy loam thrown up by torrents or floods, I have gathered it fo large, as to weigh a quarter of a pound, in the middle of a mild May, warm, with gentle showers. It is of a yellowish-white, and changes by age to a pale reddishvellow, and in drying to a straw-colour. Snails are very fond of it, and there are commonly fome within the large ones, which eat them up by degrees, if not gathered.

<sup>\*</sup> See The Description of it by M. Lyster, M. D. in his Journey to Paris.

29. There is a variety of it in the same kind of soil, and under the shade of ash-trees, in a small island formed by North Tyne, near Lee-hall, and a cottage on the brow of the hill above it, called, Carey-house, and on the banks of South Tyne, in Knar's-dale, of an ash-colour (r), changing by age, and in drying, to a rusty grey. It never arives to the size of the former, but is always small.

They are both ingredients in culinary fauces. When first dried, they give a fcent to a room like that of a strong beefgravy; and when used, taste like it, rich and high-slavoured.

go. Fatid Pseudo Morel, or Bastard-Morel (s). In the same places with the former, not unfrequent. It so much resembles them in its exterior sigure, that it is often gathered for them by mistake, or inadvertency. The head is more slender, open at the bottom, and the Cavernula more narrow and longer. The stalk is also not so robust. It is of a brown colour, with an admixture of a fordid greenish-yellow, which it retains in drying; of an ungrateful settid smell, which it likewise retains, and communicates it to a room, if stringed and hung up in ever so small a quantity. These are distinctions sufficient to know it by, not to mistake it for the genuine kinds, whose heads are always close at the bottom, and of no ungrateful scent, either in their recent or dried state.

- 31. Fatid, frow-white, Horn-Mushrome (t). This was for some years an annual production at the foot of my own garden, at the fouth-east end, at Simonburn, and was with difficulty rooted out; its stringy fibres, and globular buttons, appearing in digging three feet under the furface. It annually grows in great plenty at the east end of a plantation of firs, beach, and Scotch elms, on the other fide of the brook by the road to Hall-Barns from Simonburn, naufeous to the traveller by its fætid fmell. It comes up in April and May, in mild showery weather. The root is a round bulb, with bulbous fibres, from which rifes a thick, tall, cylindric pedicle, with a conic head, at first covered with a reticular film, like a mantle of the finest wrought-work, fnow-white, fplendidly gay, and gradually opens, and shews reticular cells of the same brightness. At first fight one cannot help admiring its beautiful form, but a near approach fenfibly convinces us of its interior qualities, and that, like fome other objects of outward elegance, it is better feen at a distance than near. After it is arrived at its maturity, it quickly languishes and melts away into a gelatinous fubstance.
- 32. Ash-coloured, crisp, laciniated Mushrome, or Curled Elvela, with a thick, wrinkled or sinuose, sistulous pedicle (u). In damp woods.

woods. Under the tall beach-trees in the plantation at Nunrvick, near the avenue, plentifully in July, especially after rains. The pedicle is thick, unequally striated or furrowed, and sistually mostly conic; but it sometimes varies in its form, and is broad, and deformed, as if two or three were coalesced or joined together. The head is one large, expanded, lacerated Lamina, of various forms, but always more smooth than the stalk, and not perforated. Sometimes the stalks are deformed and palmated at the ends, without a head, like the white coralline mushromes.

33. Ash-coloured, bicollate Mushrome, or MITRE-MUSHROME, with a slender, striated, solid pedicle (v). With the former, not unfrequent, of which it is a variety. The stalk is single, slender, moderately wrinkled or striated, two or three inches long. The head is a bicellate lamina, resembling a Bishop's Mitre; sometimes varying in its form, and running into a long convex-like shape. It is of a light grey, or ash-colour, darker towards the bottom of the stalk.

34. Dark grey, companiform, conic Mushrome, or Cornucopia-Mush-Rome (w). In woods. In the middle of the bank of wood oppo-

military-road, a quarter of a mile west from Carraw, in the fpring, plentifully, among other mosses.

- 38. Small, sessile, white, proliferous Cup-Mushrome (a). About the decayed roots of fir-trees, but not common. I observed it on those by the road in the rectory-den at Simonburu, in the spring, sparingly. It rises in the form of a small globule, and after some time opens, and shews a large cup, a quarter of an inch in diameter, of a glossy white. Other globules rise on the sides and in the center of the cup, which give it the appearance of a cup and balls in miniature. These by degrees open, and assume the form of cups. It is a beautiful species. Two or three commonly grow together, at small distances.
- 39. Tufted, yellow, clavated, coralline Mushrome (b). In the openings of thick woods, in autumn, sparingly. I met with it in one of the walks in the vicarage-wood at Hartburn. It is flattish and succulent, slender at the bottom, tumid in the middle, gradually tapering to an obtuse point, two inches long; growing in tusts, twenty or thirty, or more together, of a beautiful saffronyellow.
- 40. Branched, tufted, yellow, clavated, coralline Mushrome (c). In damp woods. At the west end of the rectory-wood at Simonburn, not
- (a) Cyathoides, quod Fungus semniser, minor, sere hemisphæricus. Raj. Syn. ii. App. p. 333. & ed. iii. p. 20. n. 21. t. 1. Michel. Gen. Pl. p. 222. n. 5.

not unfrequent in the fpring and autumn. It is from an inch and a half to three inches long, of a compressed form, and succulent, one or two branches rising towards the middle, with large clavated apices, of the same beautiful colour as the former.

- 41. Branched, white, coralline Mushrome (d). In the upper part of the bank of wood opposite to the west end of the rectory-den at Simonburn, sparingly, in autumn, among the putrid leaves and mosses. It is thick, succulent, and very much branched, three inches long, of a bright beautiful white.
- 42. Branched, gelatinous, reddish-brown Mushrome, with globose apices (e). I met with this on a fallen crab-tree at the west end of Tecket-wood, in great abundance, in autumn. It is about half an inch long, and divides in the middle into three branches, each terminated by a small pellucid globule.
- 43. Sessile, round, pulverulent Mushrome, with stellar rays (f). On dry hills, in autumn. I observed it on Glanton-pike, near Whittingham, in September, plentifully.
- p. 103. & Syn. iii. p. 16. Fungus xix. Læsel. Pruss. p. 84. Coralloides slavum. Tourn: Inst. p. 562. Muchel. Gen. Pl. p. 209. Digitellus corallisormis, luteus, minus ramosus. Martyn. - 45. Great, round, pulverulent Mushrome, with stellar rays, and a short, thick pedicle (g). On Chapel-hill, at Belsord, in the latter end of autumn. On Broadpool-common, between Con-sheels and Blake-law, near Simonburn, in September, after rains, frequent. The pedicle is about an inch and a half or two inches long. The head is very large, round, and snow-white, with many stars of a moderate size, very handsome. I met with a considerable number of them on that hill in September.
- 46. Lesser, petiolated, round, pulverulent Mushrome, with large fissile rays, and a stellate osculum (b). On the banks of the rivulet of Bramish, near Ingram. The pedicle is about an inch long. The head is round, of the size of a small pipin; the stars large, sissile, as if impressed with a tool, very beautiful. I met with great numbers of them on the banks of that rivulet in the middle of September.
- 47. I observed, at the same place, a beautiful VARIETY, of a compressed form, with broad and elegant undulations between the stars, resembling the marine Brain-Stone (i).
- (g) Fungus pulverulentus, crepitus lupi dictus, coronatus, & inserne stellatus. Raj. Syn. iii. p. 27. n. 11. t. 1. f. 1. Geaster major, umbilico simbriato. Michel. Gen. - (i) Geaster compressiformis, Astroitis marini instar, elegantissime undulatim striatus, radiis multifidis, umbilico seu osculo stellato.

48. Small turret-like pulverulent Mushrome, with fiffile rays, and a stellate osculum (k). I met with this beautiful and uncommon species on a ditch-bank by the military road, at a small distance from a remarkable precipice in the Roman-wall, called the Peel; where there were two or three of them together in September.

Mushromes increase by feed, and by their stolens or suckers, and constantly produce the same species as other plants. For the first clear discovery of their propagation by feed, we are indebted to Micheli. He not only beheld them with his microscope, but demonstrated them by experiments. He preserved and sowed several species, and brought them to perfection. For later discoveries, we are obliged to our own countryman, Dr. Hill. Before their discoveries were made, the learned Dr. Lister was of opinion, that the lamella, or gills of mushromes, were the capfula or pods for their seeds, but did not give any proof of their existence by experiments.

## CHAP. IX.

## OF BIRDS.

1. On the highest and steepest part of Cheviot, so called from its being the chief of the mountains round it, the Eagle (a) fometimes has its airy. Two beautiful ones were bred there a few years ago, one of which was shot by a gentleman's servant. A fportfman afterwards killed one of the parent-birds. In the beginning of January, 1735, a very large one was flot near Warkworth, which measured, between the points of the wings extended, eleven feet and a quarter. There was another killed, 1761, near Tindal-house, by William Carr, of Etall, Esq; They are said to be in fuch plenty in the North of Scotland, in the Orkneys, that whoever kills one is intitled to a hen from every house in the parish. It is a beautiful Bird, robust, and of a mighty spirit, and fierce nature; the hooked beak sharp and terrible, the mouth wide, the eyes large, in a kind of hollow, bright and sparkling like fire; the iris of a greenish flame-colour, the pupil black, preferved in their vigour and strength from external injuries, not only by a periophthalmium or nicititating membrane, which ferves other birds inflead of eye-lids, but also with four opercula or eyelids, two above and two under, with which it covers its eyes instantaneously, whenever it is disposed. It is so quick-sighted,

<sup>(</sup>a) Chryfaëtos. Will. Orn. p. 27. t. 1. Raj. Av. p. 6. n. 1. Charlet. Av. p. 70. n. 1. Falco cera lutea, pedibus alatis, corpore rufo. Linn. Faun. Suec. p. 18. n. 56.

that in its most towering slights, far out of human observation, it can discern the smallest thing upon the ground or in the water even the minutest of the finny race, or the youngest leverets in their seats; darting upon its prey with the celerity of an arrow. It builds in the most retired, inaccessible places, and lays four eggs.

- 2. We have the Bald Buzzard (b), so called from its yellowish-white crown, which at a distance looks like baldness, about the alpine mosses; where it is known to the shepherds and many of the common people by the name of the Bastard-Eagle. It is, indeed, so like an eagle, that it is mentioned as one by an antient and curious naturalist under the name of Halyatus (c). The eyes are not hollow as in the eagle's, but prominent; the iris of a bright sparkling yellow. The back and wings are of a dark brown; the under part of the body white; the legs and feet blue, from which it had the name of Cyanopoda given it by Gesner (d), i. e. the Blue-legged Falcon. It lives upon water-fowl, and upon sishes. It breeds annually on the mosses near Greenly-lake, among the tall herbage and junci. It lays four eggs, white, of an elliptic shape.
- 3. We have the Glead, or Swallow-tail'd Falcon (e); the only one hitherto known with that remarkable distinction, in the alpine,

<sup>(</sup>b) Balbufardus. Turn. Av. apud Gesn. Will. Orn. p. 37. t. 6. Raj. Av. 16. n. 3. Falco pedibus ceraque cæruleis; corpore supra susco, capite albo. Linn. Faun. Succ. p. 19. n. 57.

<sup>(</sup>c) Aldr. Orn. 1. 2. c. 3.

<sup>(</sup>d) Gefn. Av. 74.

<sup>(</sup>e) Milvus. Charlet. Av. p. 72. n. 14. Will. Orn. p. 41. t. 6. Raj. Av. p. 17. n. 6. Falco cera flava; cauda forcipata, corpore ferrugeneo, capite albidiore. Linn. Faun. Suec. p. 19. n. 59.

and some of the vale, woods. It is in the greatest numbers in the west and north-west parts, where many of them usually join company, and in towering undulating slights look out for young poultry, which is no sooner perceived by the old ones, than they warn their little offspring by a signal to take shelter under their wings; but the unwary wanderer is sure to be seized and carried off. It is a great destroyer of wood-pigeons, and in the scarcity of such dainties condescends to live upon mice.

4. The Dove-coloured Falcon, with black pointed wings, and the breaft elegantly variegated with brown and white in transverse lines, usually called the Hen-Harrow, and the Henharrier (f), breeds annually on Cheviot, and on the shady precipices under the Roman wall by Crag-lake, and on those of great Waney-housecrag near Sweethope-lake. The Hen is of a rufty brown, with a white fpot under the eyes; the breast and belly of a reddishwhite; the train variegated with black and yellowish-red transverse lines alternately, the red broadest; the rump white, which in flying has the appearance of a ring, from which the acquired the name of the Ring-Tail. They are feldom feen together, except in the breeding-feafon; which, with their different coloured plumage, has made them often taken for a diffinct species. The male on the approach of any body whilst the hen is with her eggs or her young, flies about in great perplexity, and makes a harsh odd kind of noise. She lays four eggs in the recesses of the steepest precipices by the lakes, and on the ground upon Cheviot, among the Erica. The young being furprized in the

These birds make great destruction of the wild ducks, and other water-fowl, that breed in the lakes, and the mountain-rivulets. They also do great mischief to the game; and of the domestic poultry they make sad havock in the spring.

new haming shade thirty mother proven

- 5. We have the *small*, brown, red-eyed Buzzard, with a yellow Cera and eye-lids, and a train shorter than the wings (g); also the rusty brown, yellow-eyed Honey-Buzzard, with a black Cera, and a grey head (b), about mountainous woods and heaths.
- 6. The Falcon, called the Keftrel (i), is not unfrequent about alpine hedges and woods, but its most favourite recess is in the solitary ruins of the old castles and towers. I have observed it in the hedges by the steep shady cliss at Tecket, and at a very near distance viewed it with a particular attention to its form and colour. It is of the size of a pidgeon. The head is ele-

gantly variegated with numerous small spots of black on a grey ground; the throat whitish; the back and cover-feathers of the wings of a yellowish red or rusty brown, punctated with black towards the ends; the breast variegated with linear, and the belly with oval, black spots on a yellowish-red ground; the thighs of the same colour, with sewer spots of black; the legs mostly naked and yellow; the fail-feathers brown, in number twenty-two; the train hoary, with a broad black fillet towards the end, which is roundish.

- 7. The Sparrow-Hawk (k) is the most common Falcon we have. It is of the size of a small pigeon. The upper plumage is of a dusky brown, with a few white spots on the wings; the under part of the neck, the breast, and belly, white, variegated with a dark brown in transverse wavy lines; the train brown, with five transverse bars or fillets of black, the wings extending only to the middle of it. It builds in the hollows of inaccessible rocks shaded with brushwood. It lays four eggs, white, with a zone or circle of red spots at the obtuse end. It is a Falcon of great spirit. It is very destructive to partridges, and the smaller birds.
- 8. The Falcon, called the Merlin (1), is frequent in woods, where it breeds. It is not much larger than a blackbird. The
- (k) Accipiter fringillarius. Bellon. Icon. 19. 6.

(1) Æsalo. Charlet. Av. p. 77. n. 5. Smerillus. Turn. Av.

beak is hooked, of a deep blue. The eyes are bright and spark-ling; the iris of a hazel-colour, the pupil black. On the throat is a yellowish-white ring, encircling the head like a coronet. The whole upper part of the body is of a dusky yellowish-red ground, variegated with black and a deep greyish-blue. The breast and belly are a yellowish-white, with brown linear spots. The train is variegated with fourteen zones of black and a brownish white; only ten of these zones in the male or tarcel. The legs are yellow; the claws of a glossy black. Age, as in all other birds, alters the colours in this; the variegations on the upper part vanishing to a dusky blue. It is very destructive to the game, at which it slies with most amazing courage and celerity, giving them a mortal wound in the neck, with one instantaneous stroke.

9. We have the great ash-coloured Shrieke or Butcher-Bird (m) in mountainous thorny thickets, and among furz. It is of the fize of a blackbird. The beak is black, hooked at the point, with a denticle on each side, as in the Kestrel and Sparrow-Hawk. The tongue is bissid or furcated at the end. The nostrils are roundish, covered with many black, short, rigid seta or bristles like whiskers. About the eyes and auricles is an oblong list of black. The head, back, and wings are of a bluish-grey. The fail-feathers are tipped with white, the outer ones shortest. The throat, breast, and belly are of a paler colour than the upper part, with a few dusky spots or undulating lines on the throat. The train, legs, feet, and claws are black; the outer toe joined

is a mark lines, the reals brown.

<sup>(</sup>m) Lanius cinereus major. Will. Orn. p. 55. t. 10. Raj. Av. p. 18. n. 3. Lanio Adder-Ber-Bird. Charlet. Av. 72. n. 13.

Ampelis cærulescens, alis caudaque nigricantibus. Linn. Faun. Suec. p. 68. n. 181.

at the bottom of the middle one by a membrane. It is a very timourous and shy bird, wary to escape danger, usually sitting on the bushes with its tail erect. It makes its nest of the heath and moss-herbage, and lines it with wool, and the downy parts of plants. It preys upon beetles, and their hexapod-worms, and grashoppers. With the cruelty of a coward it seizes upon the young of other birds in the nest. It adventures also on the parents, particularly the little harmless song-birds, wantonly murdering many of them before it tastes one, which made the salconers, who sometimes trained it to take larks, &c. call it the murdering Pie; and the common people in Derbyshire\*, Shropshire, and Cheshire†, the Wierangle, from the German name Werkangel, i.e. the sufficating Angel.

10. We have the ash-coloured Shrieke, or Butcher-Bird (n), in the same mountainous parts. It is of the size of a Bulsinch. The head is large, the beak black, and the tip hooked, with two angular appendages or denticles, without cases or cavities to receive them. The tongue is divided at the extremity into many parts, hairy, as is its receptacle, the palate. There are black stiff bristles about the nostrils as in the larger species. About the eyes and auricles is an oblong black list, and another above it of white. The head and rump are hoary; the middle of the back, and the middle series of the small feathers on the wings of a dusky greyish-red. The sail-feathers are blackish, spotted

Lanius minor (Fœmina). Raj. Av. p. 19. n. 5.

at the infertion with white. The throat, breast, and sides of the body, are of a pale reddish white; the lower part of the belly white. The claws are black, and very sharp; the outer toe connected by a membrane to the middle one.

The hen refembles the great butcher-bird in colour, and has often been taken for a distinct species. The head is cinereous. The back is of the same colour, variegated with transverse lines of black. The breast and belly are whitish, tinged with yellow, in beautiful wavy lines. The fail-feathers are mostly of a uniform blackish colour. The train is marginated with grey, and tipped with white. It builds in hollies, and the black and white thorn. It lays six eggs, white, with a circle of reddish-brown at the obtuse end.

folitary defert places. It is a bird of great beauty, of the fize of a wood-pigeon; the wings, when extended, measuring about three feet; the beak pretty large, hooked, and black; the tongue thick, and bifid at the extremity; the eyes large, the iris a beautiful yellow; the auricles large and handsome; the face adorned with a double circle of feathers, the exterior ones elegantly variegated with small linear spots of white, red, black, and yellowish; the interior mostly red; and where they meet, they are both edged with black; the back and wings have the same beautiful plumage, variegated with black, yellow, white, and a reddish-brown. The horns or auricles are composed of six feathers, above an inch long, edged with yellow and white, and black in the middle, like those in the wings. Six or seven

<sup>(</sup>a) Otus minor, capite aurito pennis sex . . . . Otus s. Asio. Raj. Ornith. p. 100. t. 12. cum bona Icone. Otus sive noctua aurita. Raj. Syn. Will. Orn. p. 64.

black, and very narrow, transverse Areolæ adorn the train, the intermediate spaces greyish above, and yellowish underneath. The feathers on the middle of the throat, and the breast, are black, variegated with white, and a reddish-brown. Those on the lower part of the belly, and on the legs, down to the claws, are of the same colour. The claws are large, black, sharp, and crooked; the middle toe, on the inside, formed edgewise; the outmost foretoe capable of being turned backwards, as in other owls, to answer the use of an anterior toe. It affects mostly to live and breed in hollow trees, and slies abroad in the evening. The bird here described was shot at Ashington, near Morpeth, and presented to me. It has been supposed not to be an English partive till of late years.

and shot on our wastes and forests where it breeds. It is of the size and shape of a cuckow; the head and auricles large; the beak small, depressed at the base, the point a little crooked, soft and black; the mouth enormously wide, set round with whisters, each composed of eight hairs or bristles. The anterior part of the head down to the back is cinereous, the middle of each feather black; the middle of the wings of a cinereous cast, the rest of the wings and back a reddish-brown, white and black, in beautiful waves, with some single larger spots, in an elegant disposition; the breast and belly adorned with short transverse areolæ of a pale red and black. The tail is near sive inches long, composed of ten feathers, the middle ones cinereous, with very narrow, transverse black saciæ; broader in the rest, and the in-

termediate

<sup>(</sup>p) Strix, Caprimulgus, Fur nocturnus. Bellon. Icon. 28. a. Will. Orn. p. 70. t. 14. Raj. Av. p. 26. n. 1. The Night-Jarr, a continuo nocte fusurro. Charlet. Av. p. 78. Hirundo cauda integra, ore setis ciliato. Linn. Faun. Suec. p. 92. n. 248.

termediate spaces cinereous, a pale red and black. The legs are short and small, feathered on the fore-side about half way, and reaching almost down to the toes, which are blackish, and the claws black, and small; the interior edge of the middle one servated, as in the heron-species. It lives on feeds, insects, beetles, and their hexapods; and is rarely seen before the evening. The bird here described was shot in Reeds-dale by Christopher Reed, of Chipchace, Esq; who sent me two of them, both young ones. Its nest is frequently found in thickets, and among brushwood.

- 13. The Royston-Crow (q) is not unfrequent in woods, and on the fea-coast. It much delights to feed upon fea-infects, and small shell-sishes; at the opening of the latter of which it is very dexterous. It takes one up with its bill, and slies to a great height with it in the air. It then suddenly lets it fall upon the fea-rocks, where it is fractured by the fall. It thus frequently provides itself with a good sish-meal. When it is tired of a sish-diet, it retires for a while into the country, and lives upon the aurelias of infects, hexapods, and stone-fruits in the woods and hedges; and for variety, upon feed-corn, and sometimes dines on grosser food with the raven. It usually builds upon aldertrees, and lays four eggs.
- 14. The fay(r) is common in our alpine woods, and deferves notice for its beautiful plumage, and active sprightliness. The head is of an elegant greyish-brown, with some linear black

fireaks;

<sup>(</sup>q) Cornix semicinereus. The Royston-Crow. Charlet. Av. p. 75. n. 2. Cornix cinerea srugilega. Will. Orn. p. 84. t. 77. Raj. Av. p. 39. n. 4. Cornix capite, gula, alis, caudaque nigris, trunco cinerascente. Lin. Faun. Suec. p. 24. n. 71.

<sup>(</sup>r) Pica glandaria. Charlet. Av. p. 46. n. 2. Corvus variegatus, tectricibus alarum cæruleis; lineis transversis albis nigrisque. Linn. Faun. Suec. p. 25. n. 74.

streaks; the beak strong, large, and black; the tongue of the same colour, bisid at the tip; the shoulders and breast of a pale reddish-brown, tinged somewhat with carmine. Fifteen of the remiges or fail-feathers in the wings are covered with some short ones of a beautiful azure, black and white in alternate lines, so glossy and splendent, as to have the appearance of a rich enamel. It lives upon acorns, and both wild and garden struits. They will come two or three together out of the wood into my little garden at Simonburn in the rasp and gooseberry-season, and can hardly be frightened away, proclaiming it, as it were, in loud clamours from tree to tree to be their own property.

15. The Green Woodpecker (s) has been observed in some of our vale-woods, but is not common. It was frequent in Dilfton-park before the wood was cut down. It is a beautiful bird, in an elegant head-drefs, a rich crimfon, or vermilion, variegated with fmall black fpots in an irregular order; the eyes bright and piercing; the pupil large, and black, with a double circle instead of an iris; the interior one of a brownish-red; the exterior white; a black lift round the eyes, with a crimfon fpot under each. The throat, breaft, and belly, are a pale green; the upper part of the neck, the back, and the fmall feathers on the wings, of a deeper and a finer green; fome of the tail-feathers of a dusky hue, with white spots, the rump a pale yellow, or ftraw-colour. The tongue is round, with a bony point, dented on each fide, capable of being contracted or extended, to a great length, at pleafure, by the help of two cartilages in mufcular cases. It darts it with a wonderful force into the barks of trees.

THE

<sup>(</sup>s) Picus viridis. HICKWALL. WITWALL. GREEN WOOD-PECKER. Charlet. Av. 93. n. 3. Will. Orn. 93. n. 21. Picus viridis, vertice coccineo. Linn. Faun. Suec. 28. n. 80.

where it pierces infects, ants, and their chryfalis, commonly called Ant's Eggs, the coss or hexapod-worms, hatched from the ova of beetles, which it often explores on the ground. It breeds in the cavernous trunks of old trees.

- 16. The great spotted Woodpecker (t), is a native of the same woods. It is somewhat larger than a blackbird; the beak more than an inch long, triangular, and channelled lengthways, tapering from a strong broad base to a point; short set or bristles slanding round the nostrils, black and curled. The eyes are handsome, the iris red, the pupil large and black; the tongue formed like that of the green Picus; the chaps streaked with white, met on each side by a transverse crimson-line from the neck in the male, but not in its mate; the interior part of the tail a bright crimson. The head is black, shaded with green; the back and exterior plumage of the wings black, the latter variegated with spots of white, and a white spot on the infertion of the wings. The bird here described was shot in Countess's wood upon North Tyne, and presented to me.
- 17. The leffer spotted Woodpecker (u) has been observed and shot in woods with the former. It is like it in shape, but considerably less; in the same rich plumage; the head and rump of the male of a splendid crimson, a peculiarity which the semales of both
- (t) Picus varius major. Will. Orn. 94. t. 21. Raj. Av. 43. 4. Charlet. Av. 93. n. 2. Picus albo nigroque variegatus, vertice nigro, rectricibus tribus lateralibus utrinque albescentibus. Linn. Faun. Succ. p. 29. n. 81.

Picus albo nigroque varius, rectricibus tribus lateralibus apice albo-variegatis. Linn. Faun. Suec. p. 29. n. 82.

are without, being only distinguished with white. The toes, the end-feathers of the tail, and the guts of all the species, are disposed alike. Two of the toes are placed behind, and two be-Fore, the lowest bones of the foretoes united. The end-feathers of the tail are all bifid, the four middle ones entirely black, strong and bending inwards, to support the body in climbing trees. The guts lie deep in the anterior part of the body, to preferve them from being hurt by the violent strokes made with the bill on trees, with the head downwards. They have this farther peculiarity, they want the Appendices of the blind guts. Their eggs are white. They are faid to make themselves a dwelling fometimes fo artfully, and the entrance fo perfectly round, in a folid tree, as not to be excelled by the most skilful geometrician. Our common people call them Pick-a-trees, also Rain-fowl, from their being more loud and noify before rain. A polite and obferving nation, the old Romans, called them by the same name, Pluvie Aves, for the same reason. It is an active sprightly bird, climbing a tree with wonderful expedition and fwiftness, never weary in feeking its living. The vermicular offspring of beetles, and small insects, are its favourite food. The bird here described was shot in Dilston-park, near Hexham.

18. The Aleyon, or King's-fifber, (v), is not unfrequent on the shady banks of our larger rivers, and deserves notice for its beauty. It weighs about an ounce and a quarter. The beak is almost two inches long, of a trigonal form, straight and sharp, and of a black colour to the corners of the mouth, which are white; the inside of the mouth yellow; the tongue short, broad, pointed, and not bisid at the tip; the eyes pretty large, and of a

<sup>(</sup>v). Ifpida, Alcyon fluviatilis, vulgo Piscator Regis, THE KINGS-FISHER. Charlet. Av. p. 3. n. 13.

piercing luftre; a red fpot between them and the noftrils, and another above them, fucceeded by a white one, shaded with red, The crown of the head is of a deep green, with transverse lines of blue. The whole upper plumage of the neck and back, to the infertion of the tail, and of the wings, a beautiful azure, bright and fplendent, beyond expression, the eye hardly able to look upon it for any length of time without being dazzled, a near attention shewing some elegant transverse strix of a deeper tinct; from the shoulders variegated with blue and green of a great lustre. The throat, breast, and belly, are a reddish-brown, on a white ground. The tail is fhort, not more than an inch and an half in length, composed of twelve feathers, of a deep blue, with a blackish cast. The legs and feet are short and small, black before, and red behind, as are the foles of the feet and back-toes; the outer toe of each foot adheres to the middle ones for the space of three joints; a circumstance very remarkable, and peculiar to this bird. We have it frequently on the banks of the rivers of North and South Tyne, where it burroughs, usually about half a yard under the furface of the earth, and lives upon fmall fishes. The banks of our other large and shady troutstreams also have its company.

19. We have the Water-Ouzel (w) in mountainous rivulets, about cataracts and water-falls, but it is not common. It is of the fize of a blackbird, but of a shorter body, and thicker neck; the beak slender, straight, and sharp, about an inch long, and black; the tongue also black, small, and somewhat bisid at the tip; the eyes large, the iris of a hazel-colour; the eye-lids encircled

<sup>(20)</sup> Merula aquatica. Will. Orn. p. 104. t. 24. Raj. Av. p. 66. n. 7. Charlet. Av. p. 115. n. 12. Motacilla pectore albo, corpore nigro. Linn. Faun. Suec. p. 82. n. 216.

with white. The head and upper part of the neck are of a rufty, brownish-black. The shoulders, back and wings, a glossy black, and deep grey, variegated; the throat and breast snow-white, edged with a pale red. The tail is short, somewhat above two inches, composed of twelve feathers. The legs, feet, and claws, are black; the outer fore-toe joined at the base to the middle one. It lives upon insects. It makes its nest in the concave parts and hollows of large rocks, with clay, moss, and the deciduous leaves of trees, of a globose figure. There was lately one on the shadowy dropping rock at Tecket-water-fall.

20. The Bittern or Bittour (x) is frequent about mosses. It is very near as large as the common Hernshaw, the beak strong at the base, straight, convex, sharp at the edges, and gradually tapering to an acute point; the tongue triangular, and short; the mouth wide, and a black spot at each angle. The crown of the head is somewhat depressed, and adorned with black; the throat and sides of the neck a reddish-brown, variegated with black, in narrow, transverse lines; long feathers upon the neck and breast, black in the middle; the exterior part of the thighs spotted with black. The plumage of the back and wings is beautiful, being cinereous, black, and a pale red, in elegant variegations. The legs are robust, long, and naked above midway up the thighs; the toes armed with sharp claws, the middle

<sup>(</sup>x) Ardea stellaris. Will. Orn. p. 207. t. 50. 52. Raj. Av. p. 100. n. 11. Ardea vertice nigro; pectore pallido maculis longitudinalibus nigricantibus. Linn. Faun. Suec. p. 48. n. 134. Stellaris. Asterias. The Bittorn. Charlet. Av. p. 110. n. 5. sequenti observatione.

 " Sect. κ."

one ferrated underneath, for holding fast its anguillaceous prey, and other lubricous sishes; the outer fore-toe united at the base to the middle one by a membrane. The back-claw exceeds all the rest in size and length. From a notion that it preserves the teeth, it sometimes has the honour of being set in silver for a tooth-pick. The eggs are of a greenish white, usually about four or sive in number, laid in a tust of moss, sedges, or rushes. The bird here described was shot in Widdrington-park, and presented to me. Most of our alpine mosses have its company. A moss to the north of Many-Laws, in the parish of Carham, is rarely without it, where it is called the Mire-Drum, from its singular loud note, especially in the spring, which is then its congratulatory ovation to its mate on the arrival of it, when there is a kind of resuscitation of beauty throughout all nature, and universal gladness.

21. The ash-coloured Heron, or Hernshaw (y), is common. It builds gregatim upon trees. On a farm of Sir Harry Grey's, by the western margin of a trout-streamlet, called Glen, under Chewiot, there is usually a fine hernery, at the vernal revolution. It is very entertaining to see the polity, the pleasures, and amusements of this pisciverous community. Some are centinels, and take their post on the side of a sunny bank, to see that no danger is near, whilst the rest of the society are at work, some in building their little temporary city, some in laying their eggs, some in attending their young, others up above the thighs in water exploring food for them, returning from the Glen, and other neighbouring streams, with a constant supply of sish-provisions. An universal harmony reigns among them; not a bird to be

<sup>(</sup>y) Ardea cinerea major. Will. Orn. p. 203. t. 49. Raj. Av. p. 98. n. 1. Charlet. Av. p. 109. n. 1. Ardea crista dependente. Linn. Faun. Suec. p. 48, 49. n. 133.

feen but contributes its utmost to the happiness of the rest, and to the prosperity and well-being of the rising generation.

22. The Black-Cock (z) is a native of our alpine wastes and forests. The head is large, the eyes of a lively and piercing aspect; the eye-brows adorned with a scarlet protuberance, bright and beautiful; the ears patulous; the beak black, and somewhat curvated. The whole upper plumage is black as jet, except some white on the wings, and a tinct of deep blue on the neck and back, extremely glossy and beautiful. The tail is forked, composed of sixteen feathers, black, and of an hoary white at the tips, the three exterior ones on each side long, and restex. The legs are feathered; the toes naked, and connected to the sinst joint by a membrane, with a cutaneous serrated edging on each side.

The Hen is of fo different a colour, that to a stranger she might feem a different species. She has the same scarlet eye-brows, patulous ears, and white in the wings, as the male; but the rest of her upper plumage is a yellowish-red, and grey, variegated with transverse lines of black; the breast, belly, and legs, hoary; the tail straight, and not reslex. These admired birds were formerly very frequent on our alpine commons among the erice, but the eager pursuit of sportsmen after them, and the burning of the erice, which afforded them both food and shelter, has made

Mares, BLACK-GAME,
Feminæ & pulli, GREY-GAME,

<sup>(</sup>z) Tetrao s. urogallus minor. Will. Orn. p. 124. t. 31. Raj. Av. p. 53. n. 2. Tetrao remigibus secundariis a medio basin versus albis, cauda bisurca. Linn. Faun. Suec. p. 62. n. 168. Urogallus minor, & Gallina Corylorum. Charlet. Av. p. 82. non specie, sed sexu tantum different.

them take refuge on the most remote and solitary heaths and mountains, and even there they are become so extremely scarce, that he is reckoned very fortunate who in a whole week's search meets with a brood. They are now as rare at the better tables, as they used to be abundant. It is the opinion of many of our alpine people, that more are destroyed in the spring, when hymenzal joy makes them searless, than at any other time, by insidious and vigilant poachers. The Black Cock, here described, was killed, 5 August, 1756. It weighed 44 ounces, and measured 33 inches between the tips of the wings extended.

instead the fleet, March establish doubter

23. The Gor-Cock, or Heath-Cock (a), is more frequent than the former in mountainous places. The wings are of a yellowish-red, variegated with transverse wavy lines of black; the breast and belly of the same colour, with large white spots. The beak is short and black; the nostrils covered with feathers; the eyebrows naked, and adorned with a carneous semilunar fringe of a bright scarlet, more broad than in the hen. It is also distinguished from her by white specks on the tips of the feathers at the basis of the beak, and a pretty large white spot on each side of the basis of the lower chap, and the deep unmixed yellowish-red on the throat, and upper part of the breast. In other

respects, they are pretty near of the same colour throughout; the tail not forked. The legs of both have a downy plumage, as well as those of the black game, to preserve them from being frozen and torped by the severity of the winter's frosts and shows.

24. The Pheafant (b), admired for its beautiful form and plumage, and for the table, is a native of our vale-woods. The beak in the more aged is whitish, with two carneous tubercles at the base, veiling the nostrils. The iris of the eyes is a splendent yellow; round which is a confiderable naked space of a bright fcarlet; the plumage between them black, with a changeable glow of purple. The ears are patulous, and the feathers near them long and elevated. The crown and neck are of a changeable gloffy green, deeper on the latter, the fides of which have a purple glow. The rest of the upper plumage is of a gloffy black or purple, as feen in different lights. The hen is not fo richly attired, being nearly of the colour of a quail. It is less frequent than formerly; owing perhaps as much to the destruction of our woods, which gave it both food and shelter, as to the unwearied pains taken by fportsmen to bring it to the table.

25. The Grey Plover, or Stone-Plover (c), is frequent on our alpine heaths, about mosses; feeding, gregatim, in August, on

<sup>(</sup>b) Phasianus. Charlet. Av. p. 81. iii.

the fruits of heath and moss-plants, small beetles and other infects. It is of the fize of a pigeon. The head and eyes are small, the iris of a hazel colour. The beak is black, strong at the base, and obtuse at the extremity; the mouth large. The head and neck are of a greenish-grey, shaded with brown, and variegated with numerous black spots. The rest of the upper plumage is of a dark brown, tipped with a greenish-grey, with some white on the edges of the fail-feathers. The breast, belly, tail, and rump, are white. The tail is about three inches long, and variegated with transverse bars of black and white. The legs are of a greenish-grey, with transverse incissures or indensings; the claws black, small, and obtuse.

- 26. The *fmall black-breafted Whistling Plover (d)* is in confiderable plenty on the wastes towards *Cumberland*. In the breeding season it deludes the boys in searching for its nest by running before them, and then taking short broken slights, alternately, till it has allured them to a great distance, when on a sudden it slies out of the reach of their observation.
- 27. The green migratory Plover (e) is frequent on mountainous heaths. It comes in the spring, and leaves us at the end of autumn. It is of the size of a pigeon. The beak is an inch long, black, furrowed at the nostrils, strong and obtuse at the points.
  - (d) Pluvialis minor nigro-flavus. Rudb. pi&.

Charardrius nigro lutescente variegatus, pectore nigro. Linn. Faun. Suec. p. 57. 156.

The

The neck is short, and the body slender. The ground-colour of the breast and of the upper plumage is black, variegated with yellowish-green spots. The belly is white. The legs are black, long, slender, and naked for a small space above the knees. It wants the back-toe.

28. The Dotterel (f), a migratory bird, exceedingly coveted by fportsmen for the table, is an annual visitant in the spring, about the middle of April. It is of the size of a song-thrush. The beak is an inch long, straight, and black. The head is elegantly variegated with black and white spots, with a white line above the eyes. The neck and back are cinereous; the wings and breast of a yellowish-red, the belly white, the rump grey. The tail is cinereous, marginated with white, composed of twelve feathers. The legs are naked for a small space above the knee, of a greenish-yellow; the claws black. It has no back-toe. It feeds, gregatim, upon beetles, and other insects. The bird here described was shot on the common between Pressen and Carham, near a large morass, much frequented by sen-birds. Most of the commons on Tweed-side have its company, particularly those of Carham and Heton.

29. The Land-Rail, Corn-Crake, or Daker-Hen (g), is frequent in our vale-meadows. It is of a flender compressed shape, and of

the quail-species, reputed their leader and guide in their migratory expeditions. It measures between the tips of the wings extended nineteen inches. The beak is short, of a livid grey colour, and furrowed on each fide towards the base. The head is fmall; the eyes are large, the iris is reddish, and the pupil black. The plumage of the head, neck, and back, are of a bright brown, elegantly fpotted with black. The wings are of a yellowish-red. The throat and breast are grev. The belly is variegated with a dark brown and white; the upper part of the thighs brown, with transverse lines of white, undulating, or wavy; the lower part naked; the legs pretty long, and of a livid colour. It is known by its note of Crex, Crex, or Crake, Crake, in loud and inceffant repetitions. In Italy, it is called, Il redelle Qualie, The king of quails \*. The quail is fourteen inches between the tips of the wings extended. The rail and it, on the approach of winter, leave us for a milder climate. The latter make the greatest part of the revenue of the bishopric of the their our the come island Caprea, near Naples +. car a large negation much fre

30. The Mountain-Finch, or Brambling (b), a beautiful bird, is one of our visitants in winter. It is of the fize of the fky-lark. The beak is half an inch long, robust, yellow, and black at the point; the head pretty large and round; the crown a glossy yellowish-red; the rest of the head, neck, and upper part of the back, a beautiful glossy black, with a changeable cast of purple, elegantly edged with a shining yellowish-red; the

base of the wings a gold-colour underneath, and of a yellowish-red above; the wings black, variegated in the middle with a transverse bar of white, and a yellowish-red; the white extended through the five fail-feathers. The tail is black, forked, and edged with a yellowish-red, in lighter and deeper shades. It is twelve inches between the tips of the wings extended. The bird here described was taken in a snare at Weldon, near Harelow-hill, and presented to me.

- 31. The Sifkin (i), an elegant little fong-bird appears by our river-fides, among alder-trees, about the fame time as the Brambling or Mountain-Finch, in great frosts and snows. It is kept in cages about Hexham for its song.
- 32. The Titlark (k) visits us in the beginning of May, if the weather is fine, and leaves us in the beginning of September. It is considerably less than the sky-lark; measures between the tips

of the wings extended about ten inches; the body flender, and the head small. The beak is half an inch long, slender, and sharp at the point; the tip of the tongue jagged; the iris of the eyes a hazel-colour. The upper plumage is black and a yellowish-green, with a cast of grey, in elegant variegations; the rump of a yellowish-green; the throat and belly white; the breaft and fides under the wings a yellowish-white, spotted with black. The tail is near three inches long, composed of twelve feathers, variegated with a yellowish-green, brown, and white. The legs and feet are yellow. It makes its nest among brushwood and furz, of moss, straw, and horse-hair. It is a merry active bird, fings upon trees; its note like the canary bird's, but shorter, and not so variously modulated. If preserved in a cage with care, it is hardy and long-lived, not fubject to colds. or cramps. In its diet, if a neftling, it must be treated like a nightingale; if an old one, like a woodlark. Its natural food in the woods are beetles, and their hexapod-worms, and other infects.

33. The Ruticilla, or the small Redstart, Red-Tail, Fire-Tail, or Star-Finch (1), a beautiful fong-bird, entertains us all summer, and disappears on the approach of winter. The beak is black and slender, the eyes of a hazel-colour; the throat and sides of the head under the eyes black, with a white spot above the eyes; the upper plumage a bright grey; the breast, rump, and tail, red. The tail is two inches and a half long. The tongue is bissed. It measures nine inches between the tips of the wings extended. It makes its nest in old walls and hollow trees, and lives upon the same kind of food as the titlark.

<sup>(1)</sup> Ruticilla. Will. Orn. p. 159. Roj. Av. p. 78. n. 5. Charlet. Av. p. 97. n. 10. Motacilla gula nigra, abdomine rufo, capite dorfoque cano. Linn. Faun. Suec. p. 84. n. 224.

It is of a timorous and shy nature, but taken young and brought up, it is very gentle and familiar; and for winter's warmth will sing in the night, as well as in the day, and learn the notes of other birds.

34. The Golden-crowned Wren (m), an elegant little bird, is a fummer-inhabitant of our alpine woods, and has been shot on the sea-coast in September, before its departure to a warmer climate. It is of the fize of the common wren, but looks less from the feathers lying closer, and fmoother. It is very near feven inches between the tips of the wings extended. The beak is near half an inch long, slender, straight, and black; the tongue long and bifid; the eyes encircled with white; an oblong fpot of beautiful faffron-yellow extended between them from the beak beyond the crown of the head, contracted and dilated at pleasure, so as either to shew or conceal its beauty. For this fingularity, the Tuscans call it the Marigold-Flower. This admired faffron-tinct is marginated with yellow and black. The fides of the neck are a gloffy yellowish-green; the upper part of the neck, and back, a yellowish-green and grey, variegated; the wings black and yellow, in a near variegation, with a narrow transverse bar of white towards the middle; the breast and belly a pale yellowish-white, with a tinge of green. The tail is an inch and a half long, grey, and edged with a yellowish-green. The legs and feet are a dusky yellow. It lives upon insects. Its fmallness, and the foliage of its favourite tree the oak, make it feldom observed. The late Francis Foster, of Felton, Esq; shot one near that place, which he presented to Mrs. Thompson of Northum-

<sup>(</sup>m) Regulus cristatus. Will. Orn. p. 163. t. 41. Raj. Av. p. 79. n. 9. Charlet. Av. p. 95. n. 1. Motacilla remigibus secundariis exteriore margine slavis, medio nigris. Linn. Faun. Suec. p. 87. n. 235.

berland-street, in Newcastle upon Tyne, in whose possession it now is, the case well preserved.

- 35. The Cross-Bill (n), an uncommon extraneous bird, was shot a few years ago by Thomas Middleton, of River-green, Esq; captain of Clissord's fort, near Tynemouth, and younger brother to Sir John Lambert Middleton, of Belsay, Bart. It chiefly frequents sirgroves for the sake of the cones, on the seeds of which it feeds. For the breaking of them, its bill seems wonderfully adapted by nature in its form and strength. It breaks off the cone, holds it up with its foot, and with its bill pares off the scales, explores the seed, and picks them carefully out. It feeds also upon hemp-seed, and juniper-berries.
- 36. The Hoopoe (o), a curious and uncommon bird, comes to us in the fpring, and leaves us in September. It weighs about three ounces. The beak is two inches and a half long, black, flender, fomewhat curvated, and fharp at the point; the tongue fhort, triangular, and tapering from a broad base to the tip. The head is adorned with a beautiful crest, composed of a double series of feathers, two inches long, extending from the beak to the anterior part of the head, raised and let fall at pleasure. They are tipped with black, partly white underneath, the rest of a yellowish-red, as is the neck. On the breast are black linear spots on a white ground, the black vanishing by age, except on the sides. The back and wing-feathers are variegated with

<sup>(</sup>n) Loxia s. Curvirostra; THE CROSS-BEAK, OF SHELL-APPLE. Charlet. Av. p. 76. n. 7. cum optima Icone, p. 77. Will. Orn. p. 181. t. 44. Raj. Av. p. 86. Coni-rosor. Rudbeck. Lapp. p. 75. Loxia rostro forficato. Linn. Faun. Suec. p. 66. n. 177.

black and white alternately; the former in little fpots, the latter in transverse lines. The tail is composed of ten feathers, about four inches and a half long, with a handsome white crescent on a black ground in the middle, the gibbose part being towards' the rump, which is white, and the horns towards the end of the tail, to which the wings nearly extend, when closed. The eyes are fmall and fprightly, the iris of a hazel-colour; the lower eye-lid larger than the upper. The legs are short and slender, the outer toe at the base connected to the middle one without the help of a membrane; the claws pretty large and sharp. It wants the blind guts as well as the wood-peckers, and feeds like them. on beetles and their hexapod-worms. It builds in woods, in hollow trees, and lays two eggs, of an ash-colour. It is very irregular in its motion in flying, as full of perplexity and difcomposure. It sits mostly on the ground; fometimes on the willow, very folitary; using a note like its name, Hoopoc, in loud and quick repetitions. The bird here described was shot in the latter end of September on the fea-banks near Chibburn, and prefented to me. Mr. Ray refers us to Northumberland and Surrey. for it \*."

Tereus is represented by Ovid as turned into this bird, and with his crest displayed pursuing his wife Progne.

- "Vertitur in Volucrem cui sunt pro vertice Cristæ
- " Protinus immodicum furgit pro cufpide roftrum
- " Nomen Epops Volucri, Facies armata videtur."

For the variety and order of its plumage, its elegant and beautiful crown, renewed every winter, the Egyptians made it the

fymbol of the feasons of the year, placed it near their mercurial crosses, on the head of their deities. Orus, the hieroglyphic of the world, had the head of one placed on the top of his staff by that superstitious nation.

37. The white Stork (p), an uncommon bird in England, was killed near Chollerford-bridge in the beginning of the year 1766, by Mr. James Moor, who keeps the noted good inn at that place. It is somewhat larger than our heron, the neck thicker, which makes it appear not so long; the body of the size of the domestic goose; three or four feet high when erect. The head is large, and a little depressed on the crown; the eyes also large, and of a piercing aspect; the beak long and robust, with a sharp point, of a beautiful red for the whole length. The legs and feet are of the same colour; the legs long and naked a great way up; the toes long; the claws black, of the shape of the nails of one's singers. The plumage of the whole body is white, except the

Hæc avis, quam fancta pietatis cultrix fit, erga parentes suas senectute jam marcescentes, notum est ex lege Ciconiarum, apud Aristophanem sæpius celebrata; quamque slagranti amore soetus prosequatur, patet ex incendio Delphensi quod dum describit Hadrian. Junius in Bataviæ Hist. cap. 17. observatum suit, inquit, "Ciconiam a pabulatione reducem, cum slammas nido suo imminentes videret, conatam omnibus pullo grandius ulos, involucres tamen, eripere mediis ex ignibus; tance dem desperata omni ope & quasi conclamata, passis alis in nidum se præcipitem dedisse, pullisque toto corpore obtectis incumbere visam suisse, veluti deposita vitæ spe, ultro cum charissimis pignoribus mortem oppetituram." <sup>(</sup>p) Ciconia. Bellon. Av. Icon. 45. a. bene. Charlet. Av. p. 108. n. 1. Ciconia alba. Will. Orn. p. 210. Raj. Av. p. 97. n. 1. Ardea alba, remigibus nigris. Linn. Faun. Suec. p. 50. n. 136. sequenti descriptione.

<sup>&</sup>quot; Alba sunt caput, collum, venter, cauda. nigræ remiges. rostrum pedesque rubri. facies magna ex parte alba."

quill and the cover feathers of the wings, which are black; the tail scarce an inch long, and not seen for the wings over it. The quills are large, making excellent writing-pens. With its bill it makes an unufual kind of noise, by striking one chap against the other, in a quick and forcible manner. It feeds upon fish, frogs, and ferpents, but will not meddle with toads. It is common in many parts beyond sea, in Holland, and Germany. It builds on old towers, and other buildings, and fometimes on the tops of tall truncated trees. The case of the bird killed here was fixed against the west front-wall of the inn, where it remained for a long time, with the erroneous name of that more rare bird, the Flamingo, put up under it in writing; a bird of quite a different figure and colour. However, this wrong name drew together crowds of people from the adjacent parts to fee it, who for fome time returned fatisfied that they had feen the Flamingo, the most remarkable bird hitherto known.

I might name some other migratory Fisipedes, as the Woodcock, &c. but as they are common, I pass on to the Palmipedes.

t. The Cormorant (a) is frequent in our larger rivers and lakes, especially in those towards the sea. Its upper plumage is a deep olive-brown, with a changeable glow of green; the breast and belly a bright white. The beak is three inches and a half long, robust, and curvated at the extremity; the upper mandible black, and serrated at the edges; the lower one compressed, and covered at the base with a naked yellow skin. The legs are strong, and armed with a kind of cancellated scales; the interior part of the claw of the middle toe serrated. It breeds upon the

<sup>(</sup>a) Corvus aquaticus. Will. Orn. p. 248. t. 63. Roj. Av. p. 122. n. 3. Pelecanus subtus albicans; rectricibus quatuordecim. Linn. Faun. Suec. p. 42. n. 116.

islands of Farn and Coquet, and other solitary retreats on the seacoast, in cavernous rocks and precipices; and sometimes upon trees, with the Heron. It was formerly trained in England, and is still in China, for catching sish. The bird here described was shot in North Tyne, near Haughton-castle, in 1762. It measured between the wings, extended, four feet, six inches, and from the points of the bill and the train, three feet, sive inches.

2. The leffer Cormorant, the Shag, or Crane (b), is frequent in the fame waters with the former. It is fomewhat larger than a domestic duck, measuring forty-four inches between the tips of the wings extended. The head is large, and depressed on the crown; the eyes fmall, and standing more forward, and lower down the head than any other known bird; the beak four inches long, straight, and slender, and of a roundish figure; the upper chap black, and curvated at the point; the under one of an olive-colour, with a cast of yellow. The body is small, flat, and depressed, like the dun-divers. The upper plumage is a gloffy black, with a changeable glow of purple and green, beyond expression beautiful, and only to be conceived by fight. The under part is brown and grey, with a black tinge under the tail, which is fix inches long. The wings extend, when closed, to the base of the tail; the legs are short, broad, compressed, and feathered down to the knees; below which they have a cutaneous, cancellated armature. The interior part of the claw of the middle toe is ferrated. It breeds annually on the island of Farn, and in other places among the rocks on the fea-coast, but most commonly upon trees. In fwimming, little more of it is to be feen than the head, erect. It is an excellent

<sup>(</sup>b) Corvus aquaticus minor f. Graculus palmipes. Will. Orn. p. 249. t. 63. Raj. Av. p. 123. Pelecanus fubtus fuscus; restricibus duodecim. Linn. Faun. Suec. p. 42. n. 117. diver.

diver, and expert in getting out of danger on the fight of a gun; becoming invisible, with the speed of an arrow, the moment the fire slashes in the pan.

- 3. The St. Cuthbert's Duck (c) is a beautiful native of the island of Farn, the monastic retreat of St. Cuthbert, with whose name it has been honoured by those two eminent ornithologists, Mr. Ray, and Francis Willoughby, Efg; who in their travels through England, heard of it no where but here; preserved specimens of the male and female being shewn to Mr. Ray by Sir William Forster, of Bambrough. They are both larger than a domestic duck; the eyes bright and piercing; the beak of a femicylindric form, obtufe at the extremity, ferrated on the fides, with a rough membrane at the base, and feathers extending from the head below the nostrils. The crown of the male is black, edged behind with a changeable glow of green; the neck, breaft, back, and three fail-feathers in each wing are a bright white; the rest of the plumage jet-black, throughout. The female is grey, variegated with brown and black fpots, with a narrow transverse line of white in each wing. They are remarkable for their foft plumage, and large well-flavoured eggs. In winter they frequent the large rivers. The male here described was shot in the river Tyne, near Hexham, in a hard frost, and presented to me.
- 4. The Sheldrake, Bergander, or Burrough-Duch (d), is also a native of the island of Farn. It is larger than a common duck.

  The
- (c) Anas plumis moliffimis, vulgo EIDER. Barth. Act. i. p. 90. Worm. Mus. p. 310. Anas Cuthbertis. Farnensis. Will. Orn. p. 278. Raj. Av. p. 141. n. 3. Anas rostro semicylindrico; ungue obtuso; cera superne bisida rugosa. Linn. Faun. Succ. p. 33. n. 94.
- (d) Tadorna. Bellon. Av. Will. Orn. p. 278. t. 70. Raj. Av. p. 140. n. 1. Vulpanser. quia in cuniculorum foveis, & rupium cavernis, more vulpis, nidulatur. Bergander. Bur-X x 2

The beak is fhort, broad, fomewhat reflected, and of a deep red colour, except the nostrils, and the extremity, which are black; a carneous tubercle between the base of the upper chap and the head, oblong, and prominent. The head, and upper part of the neck, are green, with a changeable tinge of black, gloffy and shining like Satin, at a remote view feeming entirely black; the rest of the neck a bright white; a broad fillet of a beautiful orange encompassing the upper part of the body, the shoulders and breaft; the rest of the breast, and the belly a bright white, with a beautiful black lift through the middle lengthways, terminated with a pale orange tinct under the tail. The wings are elegantly variegated with black and white, and the middle of the back is all white. The tail is white, mostly tipped with black. The legs and feet are of a pale carmine, and the skin so pellucid. that the course of the veins may clearly be seen through it. It is more admired for its beautiful clothing, than for the table; bearing no price for the table on account of its ungrateful tafte. I have feen them brought up from the egg under a common hen at Gloucester-hill, near Warkworth, out of curiosity, and for their beauty. They were as tame and familiar, as other domestic fowls. Cavernous rocks, and clefts or cavities in the earth, are the fituation it prefers to all others for breeding in. Hence it obtained the name of the Burrough-Duck.

5. The Pengnin (e), a curious and uncommon bird, was taken alive a few years ago in the island of Farn, and presented to the

ROUGH DUCK. Charlet. Av. p. 103. n. 2. Alb. Orn. p. 9. t. 94. SHELDRAKE OF BURROUGH DUCK. Dale. Harw. App. p. 405.

<sup>(</sup>e) Anser magellanicus. Clus. exot. p. 101. Anser magellanicus s. Penguin. Worm. Mus. p. 300. t. 301. Penguin nautis nostratibus dicta. Will. Orn. p. 242. t. 65. Penguin. Raj. late John William Bacon, Efq; of Etherston, with whom it grew fo tame and familiar, that it would follow him with its body erect to be fed.

6. The Coulterneb, or Pope (f), a remarkable bird, is an annual visitant of the island of Farn, where it breeds. It is less than the common duck. The beak is of a different structure from the duck-kind, of a triangular form, fhort, broad, and compressed fide-ways, curvated and sharp at the extremity, with a callous fubstance at the base, as in parrots. It is of two colours, cinereous towards the base, and a bright red at the point. It hath three or four transverse furrows in it. The eyes are large; the iris grey; the eye-lids armed with a black cartilage; a fmall carneous protuberance on the upper one, livid, and triangular; with another of the same kind on the under one, but roundish; a grey lift round the eyes. The upper plumage is black, the lower one a bright white, with an elegant black fillet or collar on the throat. The wings are very short; the tail two inches long. The legs of the old ones are red; those of the younger ones, not full grown, a bright yellow; the claws a bluish-black. It wants the back-toe. Its legs are fo short, and situated fo far backwards, like the divers, or loons, that it is with difficulty it can take wing, without the advantage of some little eminence, a stone, or a mole-hill, which makes it often a captive if surprized upon a level ground; but it does not tamely part with its

<sup>(</sup>f) COULTERNEB. TOMMY NODDY. Northumbr. Golden Head. Bottle-nose. Ebbrac. Pope. Cornub. Puphinus Anglicus. Gefn. Av. p. 725. Pica marina. Aldr. Orn. 1. 19. t. 37. Alb. Alca rostri sulcis quatuor, oculorum regione temporibusque albis. Linn. Faun. Suec. p. 42. n. 118.

liberty, giving many severe strokes with its sharp beak and claws. When it is once on the wing, it skims with great celerity on the surface of the water. It puts itself to little trouble in providing a nest to breed in, being content with any subterrene cavity, but seems best pleased with a rabbit-burrough, turning the poor animal out of its own tenement by force, if not deserted before its arrival. The legs are larger than those of a duck, of a reddish colour. It lays only one at a time, and so on to the fifth. They leave us in Angust, and return in the beginning or middle of May. Such of the young as are not able to sly, they leave behind to shift for themselves.

- 7. The Guillimet (g) breeds annually on the steep cliss of the island of Farn. It measures between the tips of the wings, extended, thirty inches. The beak is near three inches long, black, straight, and sharp at the point, with a small denticle near it, hanging over the under chap, when the mouth is shut. The whole upper plumage is a cinereous-black, the under one white. It lays very large eggs, above three inches long, sharp at one end, and blunt at the other, of a bluish-green, some of them streaked with black.
- 8. The Razor-Bill (b), is another of the Farn-island visitants in the summer. It is less than the common duck; between the

Alca rostri sulcis quatuor; linea utrinque alba a rostro ad oculos. Linn. Faun. Suec. p. 43. n. 120. The Auk. Northumbr. Dunelm. Eborac. RAZOR-BILL. Dorcestr. Murre. Cornub.

tips of the wings, extended, twenty-fix inches. The beak is two inches long, black, compressed side-ways, curvated at the point; a deep furrow above the nostrils, and between it and the base a short plumage, as soft as velvet; two more deep furrows below that, transverse, and white; and another faint one near the extremity. The mouth is a bright yellow within, like the Coulterneb's; a white lift descending from each side of the head to the angles; the upper part of the throat reddish, the rest of the under plumage a bright white; the upper one black. It and the Coulterneb, and Guillemet, are conflant companions, their wings, tails, legs, and feet, all formed alike, for fwimming, and fkimming upon the furface of the water, and not for high flights, or for walking; all wanting the back-toe; all leaving and visiting again their favourite island of Farn about the same time; all: laying but one large egg, unless stolen from them; those of this bird two inches and three quarters long, white, with black fpots, the smaller ends not so sharp as those of the Guillemet. They make no neft, but lay them on the ledges of the bare rocks. They are well tafted, and much effeemed, particularly those of the Auk.

Nor untrembling canst thou see How from a scraggy rock, whose prominence Half o'ershades th' ocean, hardy men Fearless of dashing waves do gather them.

The common fea-birds breed on the fame cliffs in great numbers \*. I had the curiofity about twenty years ago to vifit this famous bird-island, towards the middle of July, when there is the greatest shew of birds and eggs, and saw the latter lie as thick upon the rocks, and among the marine herbage, as represented

<sup>\*</sup> See Ray's select Remains. Itin. ii. p. 181, to p. 185.

by Holingshead †, and Leland ‡. The birds on being disturbed, rise, as it were, in battalia, and darken the very air, except the Coulternebs, and the beautiful Sheldrakes, Cuthbert-Ducks, and Cormorants, which take refuge in their subterrene or cavernous retreats, if they can reach them.

9. The Golden Eye (i), so called from the iris of the eyes, being of a beautiful yellow, like burnished gold; and called by the Italians, Quattro Ochii, i. e. four eyes, from a round white spot at each angle of the beak, is not unfrequent about the Farn-islands and on the fea-coast. It is short, and thick bodied; the head large, of a changeable colour, according to the lights it is viewed in, black, purple, and a grafs-green, gloffy and fhining, like filk. The neck is short, of a filvery white, as are the shoulders, breaft and belly. The wings are black and white, variegated in a remarkable manner; the middle feathers white, and the exterior and interior ones black, both in the cover and the fail-feathers. The lower part of the back is black; the tail of the same colour, three inches and a half long, composed of fixteen fea-The legs are short and robust; of a deep yellow. It measures between the tips of the wings, extended, twenty-seven inches. The bird here described was shot on the sea-coast, near Druridge, and prefented to me.

10. The Bernacle (k) is frequent near the river Tweed, and Holy Island, in winter. It is considerably smaller than a goose,

<sup>†</sup> Hol. Chro. Vol. 1. ‡ Lel. Itin. Vol. 6. p. 60.

<sup>(</sup>i) Glaucion. Glaucus. Bellon. Av. Icon. 33. 6. Glaucion Bellonii. Aldr. Or. 1. 13. c. 38. Will. Orn. p. 281. Anas oculorum iridibus flavis; capite grifeo; collari albo. Linn. Faun. Suec. p. 37. n. 104.

<sup>(</sup>k) Anser Scoticus verus Bernicla. . . . . . . Bernicla f. Bernacla. Will. Orn. p. 274. Raj. Av. p. 137. Bernicla. Bernacle. Scotch-Goose. Clake-Goose. Charles. Av. p. 103. n. 4. Anas capite colloque nigris. Linn. Faun. Suec. p. 32. n. 91.

and larger than a duck. The beak is short, broad and black. The plumage of the head, neck, and lower part of the thighs, is black; the belly cinereous; the back variegated with black and grey; the fail-feathers a dark grey; the short plumage of the wings, white, black, and cinereous, in alternate variegations. The tail is black. The back-toe is short, and slender. The case of one stuft was shewn Mr. Ray, at Sir William Forster's, of Bambrough\*.

11. The Soland Goofe (1) is often that in autumn in its way fouthward from Scotland, on the commons near the Tweed and Till, and fometimes in winter, both there and on the fea-coaft, and in other parts of the country. It is as large as a common heath-goofe, fix feet between the tips of the wings extended. The beak is long, ftraight, fomewhat curvated at the extremity, dentated on each fide, and of a deep cinereous colour. The mouth is black within. The plumage, when full-grown, is all over a bright white, except the Remiges or fail-feathers, which are black for the space of sixteen inches. The crown, and upper part of the neck, turn yellow with age. The tail is about feven inches long. The legs are feathered down to the knees, and black below; the claw of the middle toe broad, and ferrated on the infide. It hath four fore-toes, all palmated. The backplumage of the young ones is variegated with black and white. The bird here described was shot at Keeper-Shield, near Haughtoncastle, in the great snow in March, 1763, and presented to me.

12. The Wild Goofe (m), in its periodical flights fouthwards in autumn from the fens in the north of Scotland, where it breeds,

<sup>\*</sup> Ray's Topograph. Observat. Vol. 1. p. 15.

<sup>(1)</sup> Anser Bassanus. Soland-Goose. Charlet. Av. p. 100.

<sup>(</sup>m) Anser cinereus ferus, torque inter oculos & rostrum albo. Rudbeck. pict. Anas cinerea; fronte alba. Linn. Faun. Suec. p. 33. n. 92.

often alights on the commons near the Tweed and Till; the whole corpfe encamping, as it were, till their strength is renewed by rest and food. We have some of them also in winter on the same heaths, and on the sea-coast. It is of the size of a domestic heath-goose, not fed in the grounds of better culture. The beak is above two inches long, dentated on the sides, black at the tip, and towards the base, and of a saffron-colour in the middle. The eyes are large, with a white line under them. The whole upper plumage is grey; the under one white, with a cast of grey on the breast. The legs and breast are of a saffron-colour, and the claws black. The order observed by them in their long slights is very curious, rank and file, like that of Virgil's cranes \*.

13. In frosts and fnows of a long continuance, the stately Swan(n) fometimes repairs for refuge to the rivers Tweed and Till, and there receives from the sportsman the untimely fate it would escape.

## CHAP. X.

## OF INSECTS AND REPTILES.

INSECTS and Reptiles are numerous, and might fill a volume. If hall only take notice of fuch as are most remarkable for their beauty and curiosity, and shall point out in my way their culinary, medical, tinctorial, and other uses.

- I. In warm fummers, the white and fearlet Aranea or Spider (a), is not unfrequent in gardens. The legs are moderately long, white, and pellucid; the anterior articulations black. The under part of the body is of a fulphur-yellow. The upper part is white, fometimes yellowish, with a coronated circle on the back of a bright and beautiful scarlet, and within it an oblong line of a bright brown. I have often observed it in my garden at Simonburn.
- 2. The dark grey and gold-yellow Spider (b) is fometimes about old walls, and ruinous buildings. It is moderately large. The under
- (a) Araneus albicans corona coccinea in alvo ovali. Lift. Aran. 51. f. 12. Raj. Inf. p. 24. n. 12. Araneus hortenfis albus ferto dorsali cinnabarino-rubro. Frisch. Germ. 10. p. 6. t. 4. Aranea abdomine flavo; annulo ovali dorsali rubro. Linn. Faun. Suec. p. 354. n. 1227.
- (b) Araneus parvus subrusus inauratus, ipsa alvi apice insuscata, levipes. List. Aran. p. 85. t. 30. Araneus truncorum albo nigroque varius, Frisch. Germ. 10. p. 16. t. 14.

  Y y 2

  Aranea

under part of the body is of a rhomboidal or depressed shape, roundish towards the anus; of a very dark grey, elegantly variegated with a gold-yellow. The upper part is adorned with the same variegations, in beautiful wavy streaks lengthways. The legs expand transversely, at distances, variegated with the same colours, in beautiful alternate rings or circles. I met with this here described under a large coal-cinder on a stone-wall at the Roman station of Caervorran. I have had these two many years in spirits.

3. The fubglobose yellow Spider, with black spots (c), is not unfrequent in tonsed hollies, and other close headed shrubs, in gardens. The thorax is of a pale yellow, with a streak of black on each side; the rest of the body of a pale or greenish yellow, elegantly spotted with black. The semale sits over her ova in a loose net of her own weaving, and though timorous at other times, with difficulty is then made to move, and shun danger. I met with this here described in the head of a variegated holly.

These little creatures are patterns and models of industry, and curious reticular works, excelling sometimes the finest gawz; furnished with materials out of the store-house of their own bodies; bestowed by nature to enable them to get their living, and with which both gloves and stockings have been made by the French virtuosi\*.

<sup>\*</sup> Reaumer. Inf.

- 4. The fearlet Aranea, Tant, or Lady-Bug (d) is often feen in gardens and fields, walking abroad out of the earth among the plants and herbage on a bright day.
- 5. The Hornet (e) is rarely feen with us, except in a very hot fummer. It is a formidable, but beautiful apis; the colours a bright yellow, red, and green, and black; the thorax black, and some of the rings or circles elegantly pectinated. A large commonwealth of them was discovered in the hollow of an oaktree, by the very brink of North Tyne, in Brome-haugh, near Chipchace, in the year 1762, a remarkable hot fummer; and on the 30th of August a period was put to it by suffocation with lighted flraw, for the fake of feeing their mechanical skill in the structure of their combs. They were fix in number; one of the outer combs meafuring twenty-one inches in circumference, the middle comb nineteen inches and a half; the other combs gradually lefs; the waxen cells extremely thin and fine, elegantly variegated with a light and deep brown; many of them measuring an inch and an half in depth; those in the least outer comb empty; a numerous vermicular generation in all the rest, covered at the top with a thin film of a pearl-colour, round and prominent, gloffy and shining, like polished pearls. So many ranges of combs, constructed with fo much beauty, and with the art. of the nicest geometrician, is a surprizing spectacle! So noble a

<sup>(</sup>d) Araneus exiguus coccineus vulgo ANGLICE a TANT dictus. List. Aran. 100. f. 38. Raj. Ins. p. 41. n. 38. Araneus ANGLICUS coccineus minimus. Petiv. Mus. p. 65. n. 701. Acarus terrestris ruber; abdomine depresso. Linn. Faun. Suec. n. 348. n. 1200.

piece of architecture cannot be viewed, or reviewed, without admiration, and a profound reverence of that Being who is the fountain of wifdom. I am obliged for this curiofity to my refpectful friend, *Christopher Reed*, of *Chipchace*, Efq; who first discovered it, and was present with me to see it carefully taken out by his fervants.

- 6. The blue and gold-yellow Apis (f) is fometimes about broken clay-banks or fcars, by waters, and old ruinous buildings, in warm places, but is not common. It is superior to all the beetribe for beauty. It is smaller than the common bee, the thorax and the head blue, very splendent, with a small tinct of green, the body yellow, like burnished gold for lustre, the wings brown, the antennæ black, with twelve articulations; the last segment of the body but one, and the thorax dentated behind. It stings like the common bee.
- 7. The *fmall black and yellow Apis* (g) is frequent in gardens, and about old houses. It is a fmall, but beautiful insect, of the wasp-kind; the thorax, head, and antennæ black; four of the articulations or segments of the body of the same colour, with annular golden fasciæ, glossy and splendent. Though it is so small, it will assault and kill a common domestic slie three or four times as large as itself, and drag it with ease to its recess.
- (f) Vespa argillacea variegata s. superbe colorata. Frisch. Germ. 9. p. 19. t. 10. f. 1. Apis parietina nitida, collari cærulco, abdomine aureo. Linn. Act. Ups. 1736. p. 28. n. 5. Apis nitida; thorace viridi cærulco, abdomine inaurato. Faun. Suec. p. 302. n. 1004.
- (g) Apis nigra; tibiis ferrugineis, abdomine maculis utrinque quatuor flaves. entibus. Linn. Faun. Suec. p. 303. n. 1011.

- 8. The finall black Apis (h) is not uncommon in gardens. It is about half the fize of a pifmire. It inferts its ova by terebration on the stems and branches of garden-roses, in a patella-like form, which, when they are in vermiculo, are stilled by the famous naturalist, Dr. Lister, the English Kermes, for giving a rich scarlet or purple dye, without the extraneous aid of an acid to six it †.
- 9. The large bluish-black and yellow Libella (i) is frequent by brooks and rivers in June and July. It is a beautiful infect. The face is of a bright yellow, with two narrow transverse lines of black, and one larger of black on the upper part. The scutellum is black, with golden specks. The wings are of a yellowish-white, transparent, and full of nerves. The body is thick and cylindric, of a bluish-black on the upper part, and yellow underneath; the two colours meeting on the sides in elegant denticulations.
- 10, 11, 12. The bluish-green Libella with yellowish-brown wings (k); the Mazerine-blue Libella, with bluish-black wings (l); the green Li-

bella with yellowish-brown wings, with a white spot at each of the apices (m), are common by shadowy running streams in the warm summer-months, with many others of considerable beauty.

They are generated under water, enclosed in a membrane. Their flight is flately. Their bodies are composed of rings to give celerity to their motion.

- 13. The *small black Elater*, with black antennæ, and a red thorax (n), is only feen with us in warm fummers. It is adorned with a beautiful red lunulated fpot on the back, turned towards the head; the exterior wings bluish, and striated.
- 14. The black Elater, with a splendent yellowish-green on the exterior wings and thorax (o). The antennæ of the male are curiously pectinated. The wings of the female are more tinged with green, and the thorax with yellow, which is the difference of colour between them.

The *Elaters* are flingless and harmless, sprightly and active infects, of a nimble wing; and delight much to rest on a dry wall, on the sides of pales, or a tree, in the fun-shine.

- 15. The orange-yellow and white Butterfly (p) is frequent in warm shady vales in May and June. The head, antennæ, and body, are of a lead-colour; the upper wings white to the middle, succeeded by a beautiful bright orange on both sides to the margin, which is decorated with an olive-green and white, alternately. The under wings are white above, and elegantly marbled and variegated underneath with a sea-green and white. It is one of our first Butterfly-visitants in the spring, making its appearance in May.
- 16. The small fky-blue Butterfly (q) usually appears in the latter end of May, or beginning of June, in warm vales. It is a beautiful insect, of a nimble wing. The head, antennæ, and body are a dark grey; the wings externally a sky-blue, edged with a narrow white fringe; and adorned underneath with numerous little eyes, black, circled with white, variegated near the margin with spots of orange, on a bright olive-ground.

- 17. The gold-yellow and brown Butterfly (r) is frequent in shadowy mountainous pastures in July and August. The upper wings are of a bright gold-yellow, elegantly waved with a dark brown; a beautiful eye, white, with broad circles of black near the tips; four of the same kind, but smaller, near the extremities of the under ones; which are bordered with narrow semicircular lines of black, a yellowish-brown, and a pale yellow. It delights much to rest on dry banks, stones, and rocks.
- 18. The finall yellowish-red Buttersly, with black spots (s), appears in shady vales and pastures, in the latter end of May, or the beginning of June. The body and antennæ are black; the upper wings of a yellowish-red, glossy and splendent, like a rich sattin, spotted with black, and edged with a deep brown; the under wings of a dark chesnut-colour, with a narrow border of a bright yellowish-red, elegantly spotted with black at the extremities.
- 19. The large stately Buttersty, called The Admiral (t), is a visitant of gardens and fields in the harvest months. It measures between the

the tips of the wings, extended, three inches. The body, and exterior parts of the wings are black, glossy and shining, like velvet; irregular bright white spots of different sizes near the tips of both the upper wings; a broad line of a deep beautiful scarlet through the middle of each, met by a broader of the same colour from the extreme margin of the under ones, which is distinguished by an elegant series of small round black spots, and a little pectinated at the edges. From this irregular circle of bright scarlet, on a black velvet-ground, it obtained the name of the Admiral. I have observed it in my own garden to have a particular liking to the yellow Martagon-lilly, of a strong fox-like scent, to which it would always return after frequent interruptions, on one of which I caught this here described under a fine net.

The Eruca is adorned with small points of white on a black ground, with small streaks of a pale red on the sides, indented above the holders, which are bristled. The chrysalis is cinereous. Both it and the Eruca sometimes vary in colour.

a lit said campi apag ad end , little

20. The tortoife-shell Buttersty (u) is not unfrequent in alpine woods and shady pastures, in July and August. I have also observed it in gardens.

21. The lesser tortoise-shell Buttersty (v) is frequent in fields and gardens. It measures between the tips of the wings, extended, two inches. The body is black, the fore-parts of both the upper wings variegated with streaks of black and a pale yellow alternately, terminated by a white speck; three black spots below, on a red ground, with a beautiful bright brown next the body; the red at the extremities bordered with a black list, with a series of indented specks in it of a sky-blue, succeeded by another black one, edged on both sides with a light yellow, in an elegant pectinated form. It frequently out-lives the winter by concealing itself in private recesses, where neither winds or rains can hurt it.

The Eruca is of a deep olive-colour on the upper part, a feries of black fpots down the middle, one on each joint; the fides edged with a pale yellow line; underneath another feries of black fpots, fmaller, on a light hair-coloured ground; the holders briftled. The chryfalis is a reddifh-brown.

- 22. The tortoife-shell Buttersly, with laciniated wings (w), is not unfrequent in vale-meadows, and gardens, in August.

Albin. Ins. t. 4. s. 5. Papilio tetrapus; alis angulatis sulvis nigro maculatis; secundariis v. albo notatis. Linn. Faun. Suec. p. 234. n. 775.

23. The peacock's-eye Butterfly (x), called by a curious foreigner, The Queen of Butterflies\*, is often feen in fields and gardens in the warm fummer-months, and, in cold ones, in close retreats. It measures between the tips of the wings, extended, somewhat more than three inches. The body is a fine brown. The edges of the upper ones next the head marbled with streaks of black and a straw-colour, with a large and beautiful eye or moon near the tip of each; a large eye or moon on each of the under wings, the extremities adorned with a beautiful brown, and pectinated. From the resemblance of these eyes or moons to those on the Peacock's tail, it had its name of The Peacock's Eye.

The Eruca is adorned with numerous minute specks of white on a black ground; the head jet-black; the holders a light brown, and briftled; the chrysalis a pale green.

Moths of considerable beauty are sometimes observed with us in warm summers. They are distinguished from Butterslies by their Antenna, which are attenuated to a point; those of Butterslies being clavated. There is another generical distinction in a species of them more remarkable. The crown and face resemble those of an owl, with a thick plumage on their legs. They are lucifuga. They sly abroad only in the evening and still silence of the night, not seen in the day, unless disturbed in their recesses.

24. The large and beautiful moth, called the Bee-Tiger (y), was taken some years ago in one of the rooms at Felton-hall, in October. It is now in the collection of Mrs. Thompson, in Northumberland-street, in Newcastle upon Tyne.

25. The white, black, and yellow Moth (z) is frequent in gardens and hedges in the beginning of fummer. The upper wings are elegantly variegated with a bright yellow and black, in spots and waves, on a white ground; the under wings white, spotted with black; the body of a bright yellow, with black spots.

The Eruca is briftled, as black as jet, with elegant circles of a bright yellow. It usually lives all winter in secure and warm retreats, and in the spring ventures abroad into gardens, and regales on the tender buds of gooseberry and currant-trees. I have found it wandering on the tops of our mountains in summer, ravaging the blossoms of the Erica and Vaccinia. The Chrysalis is of the same colour, very handsome.

The moth here described, appeared in June, from a chrysalis in my study-window, making its way out of a straw-coloured silky clue at the obtuse end. It was assaulted on its first appearance by an insidious and furious spider, and preserved by my accidentally seeing it, after it had made a better desence than

could well have been expected in its weak and feeble state, before its moist wings were dry and unfolded. In about half an hour after, it was vigorous and sprightly, and seemed by its motions to exult under its resuscitation from its reptile state to a volant one, capable of surveying by gentle slights every beautiful vegetable, and regaling on their velvet buds and blossoms.

26. The small, beautiful, red and dark brown Moth (a) is frequent in vale-meadows, in June and July. The head, antennæ, and body are black. The under wings are of a deep beautiful red, with a narrow edging of a dark brown. The upper wings are of a fine umbre-brown, with a beautiful streak of deep red on each of them, lengthways, near the edges, with two orbicular spots of red at the tips. I caught this here described on the south side of the vicarage-garden at Haltwesel.

The Eruca is of a deep orange-colour, with circles of black. It lives on the Ragwort. The chryfalis is of the fame colour.

- 27. The gold-yellow and brown Moth (b) is not unfrequent in gardens. It is exceedingly beautiful; the plumage of the face of a

of the wings, extended, three inches; the face broad and round, of a light yellow, with three beautiful circles of brown and yellow alternately; a filvery plume on the head, erect; the body a straw-colour with black circles. The upper wings are a silvery grey; three transverse wavy lines towards the head, brown and yellow, alternately; a large space of a beautiful straw-colour towards the extremities, with three irregular wavy circles of brown and yellow, in an alternate order, extremely elegant. The legs are feathered down to the very ends, like those of a dove; the feathers long, and as white as snow. This, here described, was found under the foliage of some wild plants at Chipchace, and presented to me by Mrs. Reed.

The Eruca is a gay little creature; the face black, with a narrow forked line of white; a lunar circle of red on the crown; the holders black and briftled; the upper part of the body striated with longitudinal lines of black and a pale yellow, with transverse ones of red; a series of shining black spots on the joints, on each side. The foliage of the willow is its favourite retirement and food. The chrysalis is red, shaded with black.

31. The brown and gold-yellow Moth (f) is not unfrequent in gardens, under weeds. It measures between the tips of the wings, extended,

Goed. p. 192. t. 80. Phalæna pectinicornis elinguis villosissima cinerea; alis exterioribus lineolis obsoletis nigris maculaque duplici pallida. Linn. Faun. Suec. p. 256. n. 829. Buff-Tipped Moth. Wilkes. Ins. t. 6. f. 7.

A a a rioribus

extended, fomewhat more than three inches. The upper wings are a dark brown; the under ones a bright gold-yellow, with a broad streak of black near the extreme margin.

32. The brown, white, and red Moth (g), is also frequent under the leaves of garden-plants. It measures, between the tips of wings, extended, three inches and a half; the face broad and round, of a dark brown, edged with a circle of red. The head is adorned with a dark brown plume; the upper wings marbled with white, and a dark brown; the under ones red, with black spots; the body red, with circles of black; the plumage of the legs of the same colours, in rings or circles.

The Eruca is large, and briftled; the upper part black; the fides, and feta, or briftles, next the head, an orange-colour; a feries of white fpots on each joint. It is frequent in gardens, and has an extraordinary affection for table-fallads, and kitchengreens. If at any time it is in danger, it rolls itself up into an orbicular form, with the briftles erect, and as foon as its first fright is over, it makes the best of its way to some shady recess for fafety. The prickly covering is given it by our wise creator to deter birds from preying upon it. The chryfalis is red, with a deep shade of black.

rioribus flavis, margine nigro. Linn. Act. Ups. 1736. p. 124. n. 60. Phalæna seticornis spirilinguis; alis incumbentibus; exterioribus cæssis nebulosis; inserioribus luteis, sascia atra marginali. Faun. Suec. p. 268. 11. 870. Albin. Ins. 72. f. C. D.

(g) Phalæna major, alis amplis oblongis albicante & fusco coloribus pulchre variegatis, interioribus rutilis cum maculis nigris. Raj. Ins. p. 151. n. 3. List. Goed. p. 219. f. 99. 33. The beautiful white and blue Moth (b) is formetimes observed by the fides of moift groves, and near hedges, under the fhade of willows, and other aquatic trees, but is not common. It measures between the tips of the wings, extended, three inches! The face and head are large, covered with a thick and beautiful plumage, white, fpotted with a deep blue. The upper wings from the infertion to the middle are elegantly marbled with the fame colours; and from the middle to the extremities of a bright grey, pellucid, and full of nerves of a straw-colour, fomewhat prominent. The under wings are also a bright grey, transparent, and full of the same kind of nerves. The body is adorned with broad circles of a deep blue and white, alternately, interfected by two blue longitudinal lines; the plumage raifed, and looking like the fringed margin of a rich robe. The legs are adorned with long bright white feathers to the very tips, and with a feries of deep blue spots. The blue vanishes into a black, and the white into a grey colour, by being exposed to rains and weather, which are as injurious to the beauty of this fair part of the creation, as to an Anemone, a Ranunculus, an Auricula, or other admired flowers in gardens. I have therefore given defciptions of fuch only, whose plumage and colouring were in their native gaiety, in their full beauty and perfection, without blemishes. I met with this moth in July, 1761, among some tall herbage by the fide of the grove, on the left hand, within the gate, in going to Nunwick-Hall.

<sup>(</sup>b) Phalæna major pulcherrima, alis amplis; exterioribus cinereis maculis & lineis eleganter depictis. Raj. Inf. p. 153. n. 5. Lift. Goed. p. 59. t. 20. n. 6. c. Phalæna pectinicornis elinguis; alis deflexis albidis diaphanis; vasis obscuris. Linn. Faun. Succ. p. 252. n. 819. VINULA. ibid. Albin. Inf. t. 11. f. 15. Puss-Moth. Wilkes. Inf. t. 12. f. 2.

The Eruca, for its majestic form, and beautiful colours, is called The Beau\*. The belly and fides are a yellowish green, parted by a longitudinal line of deep purple, with a feries of fmall, oblong, white spots, one on each joint, in a regular order, and a fhort feries of small round eyes above it, and more irregular; a deep purple, circled with white, one larger than the rest, and standing lower. The upper part, from the head to the tail, is of a bluish-green, with bright white spots, like a beautiful mantle, or cloak loosely cast over it, with a graceful ease, edged with purple and white, seeming as if sastened under the first pair of holders, and with two large purple spots at each angle or corner of the head, and a smaller on the most prominent and elevated part of the neck, contracted, and held up, as it were, to shew the beauties underneath. An elegant broad golden circle is round the face; a deep velvet-rose colour within, a short narrow line of black down the middle, with an edging of yellow. The forefeet are black, elegantly spotted with white. The tail is long, and forked, with the same variegations to the middle, and of a rose-colour to the extremities. It protrudes and draws in its tortoife-like head at pleafure, under its rofecoloured embroidered veil. If molefted, or provoked, it infantly shews its refentment by unsheathing a pair of scarlet points at its tail, which, when touched, are foft, and feem not defigned to do mischief. So that it is as harmless, as it is beautiful. The foliage of the willow, and poplar, are its favourite refuge and food. The chryfalis is large, red, and shaded with black.

Vagipennia, or infects with case-wings, of beauty or curiosity, are not observed with us in any great variety.

<sup>\*</sup> Eruca bicauda elegantissima, VINULA dicta. Raj. Inf. I. c. n. 3. Vide, Albin. 1. c.

34. The chefnut-brown Beetle, or Hedge-Chafer (i), in very warm fummers appears in shady vales, by the sides of brooks and ftreamlets, and fometimes is heard buzzing against the windows of our houses,—Alis tonans. Hence it is called by the French, Ali-The Elytra, or cafe-wings, are a chefnut-brown, the lateral fegments of the wings white, the thorax hairy, the tail curvated. By the direction of Providence, Chafers were frequently a feourge to the Jewish nation, disrobing the trees and fields of their verdure, bloffoms and fruits, leaving defolation and destruction behind them \*. They appeared in formidable numbers in Ireland in a hot fummer, and committed great ravages †. Their Erucæ are frequently as destructive. Whole meadows and cornfields were destroyed by them in Suffolk, in 1747. The decrease of rookeries in that country was thought to be the occasion of it; those hexapods being the favourite food of rooks, which they fearch after with indefatigable pains ‡: The many rookeries with us is partly the reason why we have so few Chafers, even in the hottest summers; seldom more than one or a pair being seen at a time.

35. The fmall Beetle with red Elytra, and a black head and thorax (k); is frequent in woods.

<sup>(</sup>i) Scarabæus arboreus vulgaris major. Raj. Inf. p. 104. n. 1. Scarabæus arboreus major castaneus. Petiv. Gaz. p. 29. t. 19. f. 2. Scarabæus maximus rusus urhopigio deorsum instexo. - 36. The finall, green, purple, and gold-yellow borned Beetle (1), is fometimes, but rarely, on heaths and mountainous pastures, in June and July, in warm summers. The head, face, thorax, belly, and legs, are of a beautiful purple, bright and shining, like silk. The Elytra are of a grass-green, elegantly spotted with a gold-yellow. The clavated Antenna or horns, and the eyes, are a glossy black; the latter full and prominent. I met with this here described in the rectory-den at Simonburn, in a remarkable warm summer. I have since observed it on Wark-common, among the heath, near Woodley-Sheels, in Tynedale, in July.
- 37. The beautiful infect of the Scarab or Beetle-kind, called *The Henbane-Cimex (m)*, from its favourite plant the *Henbane*, is frequent under its foliage in the latter end of May. The head is black, with a red fpot in the center. The *thorax* and *fcutellum* are variegated with red and black; the elytræ are red, with two black fpots in the middle; the wings under them are brown; the antennæ and legs black; the trunk composed of four joints.

List. loq. p. 39. n. 39. mut. t. 31. f. 21. Cimex hyoscamoides ruber, maculis nigris. Pet. Gaz. t. 66. f. 2. Cimex oblongus rubro nigroque variegatus, alis susci immaculatis. Linn. Faun. Suec. p. 208. n. 665.

The ova of this elegant little infect are tinctorical, and yield an exquisite vermilion, not volatile and fugitive, but fixed and permanent, equal to cocheneil, even when assisted with an acid salt. They are oblong, and first of a light orange, and afterwards of a deeper colour, as the young come to maturity, which are not vermicular, but come forth perfect cimices. The tinctorial virtue is the richest when the ova have acquired their full orange-colour. Urinous salts and alcalies change it from a vivid crimson to an obscure colour, between a violet and a purple.

among dust, and in decayed rotten wood, lonely and retired. It is one of the smallest of the Vagipennia, of a dark brown, with irregular light brown spots, the belly plicated, and the wings under the cases pellucid, like other beetles, the helmet turned up, as is supposed, for hearing; the upper lip hard and shining. By its regular pulsations, like the ticking of a watch, it sometimes surprises those that are strangers to its nature and properties, who fancy its beating portends a family-change, and the shortening of the thread of life. Put into a box, it may be heard and seen in the act of pulsation, with a small proboscis, against the side of it; for food, more probably, than for hymenzal pleasure, as some have fancied.

Reptiles furnished with shells, as the land, pond, and river-cochlea, are found in considerable numbers.

39. In winter, the great Garden-Cochlea (o), is usually seen hanging in clusters in the cavities of the rocks at the Hermitage, near Wark-

<sup>(</sup>n) Scarabæus galeatus Pulsator.

<sup>(0)</sup> Cochlea citrina aut leucophæa, non raro unicolor, interdum tamen unica, interdum etiam duabus, aut tribus, aut quatuor, plerumque vero quinque fasciis pullis distincta.

Warkworth. It is of a chefnut-colour, marbled with yellow. With broad fasciæ or belts, and five convolutions. A thin pellucid film ferves for an operculum at the mouth to keep out the cold, made by the little creature with the same materials that it makes and repairs its pretty dwelling, the gluten out of its own body. Statuaries and china-menders pierce it to get the sanies, which they mix with whites of eggs, and quick-lime, and grind all together, as we do paint, till they are incorporated, and fit for use. Fractured marble, and china, are put together with the greatest expedition and firmness with this composition. The statuary, the pictorist, and medalist, also apply the sanies of this reptile to their molds, before they take off the impressions with wax, making the waxen sigures come off with more ease, and with a finer skin.

40. Under the fallen leaves and mosses, upon old shadowy stone-walls, topped with earth, the elegant little torcular Cochlea (p) is not unfrequent. I met with it in considerable plenty on one at Simonburn, opposite to St. Mungo's Well, on the north side of the rivulet. It is straight, and slender, half an inch long, mucronated, with eight convolutions, of a bright chesnut-colour. The lubricous, cornuted tenant within is a dark grey.

List. Angl. p. 116. t. 2. f. 3. Cochlea interdum unicolor, interdum variegata, item variis fasciis depicta. Ejusd. Hist. Conchyl. t. 1. n. 54. Cochlea vulgaris, testa variegata. Petiv. Mus. 5. n. 14. Act. Ups. 1736. p. 41. n. 20. Cochlea testa pellucida oblonga, spiris decim sinistrorsis, apertura subrotunda. Faun. Suec. p 372. n. 1300.

41. In winter, under stones, near the banks of alpine brooks, and in summer, in moist places, the small, depressed, umbilicated Cochlea (q), is often observed. It is half an inch broad, with four wreaths or convolutions; of a light brown colour, and pellucid; the apex prominent on the upper part; a small round cavity, or umbilicum, underneath. The little animal carries it upright in crawling, and is itself of a sine blue colour, tinged with white. It is the favourite food of the Song-Thrush, which takes it out of the shell with great dexterity, by breaking it at the apex.

42. The large fresh-water Turbo, with six wreaths (r), is plentiful in Shilden-lake, near Corbridge. It is two inches long, with six wreaths; of a light brown colour, and pellucid; the operculum large, oval, and testaceous. The horns of the limax inhabiting it are two, mucronated, and sometimes branched like those of a deer; two small black spots standing at their base, which are its two eyes; and behind them two small auditorial or branched apertures.

<sup>(</sup>q) Cochlea pulla sylvatica, spiris in aciem depressis. List. Angl. p. 126. t. 2. f. 14. Cochlea nostra umbilicata pulla. Ejusa. Hist. i. p. 29. f. 62. Cochlea testa producta cuminata opaca, ansractibus senis subangulatis, apertura ovata. Linn. Faun. Suec. p. 374. n. 1310.

- 43. The small fresh-water Turbo, with five wreaths (s), is not uncommon. I met with it in the bottom of a spring under my garden at Simonburn, in great numbers. It is half an inch long, with sive wreaths; the mouth small, and oval. It is covered with a thin argillaceous kind of crust, which is not easily taken off; the operculum rough, and testaceous. The horns of the limax belonging to it are very small and short.
- 44. In the same lake is the Turbo with four wreaths, a remarkable large mouth, and a short acute apex (t). It is an inch long, and half an inch broad; of a light brown colour, pellucid, with four wreaths. The limax within is yellowish; the two horns short, broad, and mucronated; two small black punctules at their base, which are its eyes.
- 45. In the pond behind the rectory-house at Simonburn the small Turbo with three wreaths (u) is plentiful. It is half an inch long,

with three wreaths; the operculum large, and oval; the apex very fmall, and more obtuse than the last; of a yellowish-brown, sometimes tinged with white, and pellucid. The horns of the limax inhabiting it are short, broad, and mucronated.

46. I met with the depressed, orbicular, fresh-water Cochlea, with four wreaths (v), in great numbers, in a small piece of water, in a meadow on the banks of North-Tyne, called Brome-Haugh, near Chipchace. It hath four elegant wreaths or convolutions, of a blackish-brown. The limax inhabiting it is of a tawney black, with two reddish horns. In warm, pleasant weather, it sails about on the surface of the water with its shell erect, very much resembling the Sea-Nautilus in its motion. It is the only one of the aquatic Cochlea that will yield a fluid on an injection of a grain of salt, pepper, or ginger, into its mouth, or by laceration, or piercing. The fluid it gives is a fine scarlet, but of so fugitive a nature, that no acid or astringent has hitherto been found sufficient to preserve the elegancy of its tinct, and from turning to an unpleasant rusty hue.

Naked amphibeous reptiles, whose lungs are so formed that they can live for some time under water, as well as upon land, are less common with us than in the southern counties.

47. The Viper (w) is fometimes observed at the roots of trees in woods, and among rocks on warm heaths, and under hedges.

An

<sup>(</sup>v) Cochlea fusca, altera parte planior & limbo insignita quatuor spirarum. List. Angl. p. 145. t. 2. f. 27. Cochlea susca, limbo circumscripta. Ejusd. Hist. 2. t. 138. f. 42. B b b 2

An oil made of it, applied externally, and fallad-oil taken internally, have been found by experience to be an effectual remedy; against its poison.

- 48. The Blind Worm (x), so called from its being erroneously thought to have no eyes, is more frequent than the viper, on warm sunny banks, in pastures and gardens.
- 49. The Water-Salamander, or Water-Lizard (y), is not uncommon in ponds, and ditches. It is remarkable for the transparency of its skin and vessels. In its body are two long Sacculi aerii, on which the blood-vessels are curiously ramified. The circulation of the blood may be seen by a microscope as plainly as water running in a river, and more rapidly than any common stream \*.
- 50. The green Lizard (z) is often observed upon alpine heaths at the bottom of the erica.

Marine Infects are frequent among the fea-rocks, and on the shores, after high spring-tides, and storms.

- 51. The finall Sea-Star, with thirteen obtuse rays, of a reddish brown colour (a), has been found among the rocks at Newbiggen. I have one with sourteen rays, or arms, of the same colour, from the shore of the bishopric of Durham.
- 52. The Sea-Star with five rays (b) is common among the fearocks at Hartley, and among many other rocks on the coast.

The Sea-Stars move in all directions. They have the power of fixing themselves to any thing at pleasure with their claspers or tentacula, which serve also for instruments to get their living. When they have found their prey, they inclose it in their arms, as in a net, and convey it with great dexterity to the mouth, which is in the center.

- on the waves, is often cast on shore by the tides. I have seen it in great abundance on the sands between *Cresswell* and *Druridge*. It looks like a mass of jelly, orbiculated and convex, whitish and femipellucid, plain underneath, with an echinated circle, adorned with whitish-brown radii. There are several varieties of it †.

SEA-BLEBS. Lancestr. Dr. Leigh's Lancashire, p. 133.

54. The fmall red Sea-Nettle (d) is frequent on the fea-rocks, and pebbles, to which it fixes itself with its claspers as firm as a limpet, in a convex form. It opens and expands itself like an anemone, or a flower of the composite order, of various tincts. It hath a conic protuberance in the center, which is the mouth. The leaf-like fibres are the tentacula or feelers with which it explores its food, and by its contractile power encloses it as in a net, like the Sea-Asters. Some of them are of a crimson colour at the time of their expansion, and others of a dark red; all of a dull obscure red colour at the time of their being contracted, and at rest. I had great pleasure in observing them unfold their beauties, and method of subsisting on the rocks, at Hartley, near Seaton-Delaval, 23 August, 1762, in company with Sir John Hussey Delaval, Bart. and his brother, Edward Delaval, Esq; F. R. S.

One was in the narrow finus of a rock, adhering to one fide of it; the exterior colour a dark red; the numerous feelers of a lively ash-colour, in continual motion towards several very small limpets and muscles round it, as if feeding upon them.

Another was fixed to the end of a pebble, of a crimfon colour in its expansion, the central protuberance having three different shades, a light and a deep orange and red.

There was also one affixed to a large rock of a beautiful red rose-colour, encircled at the edge with little oblong tubercles of a bright Azure. A small limpet being placed near it, and in a few minutes touching it with its horns, it seized upon it instantly

Urtica rubra. Rondelet. lib. xvii. c. xvii.

<sup>(</sup>d) Urtica rubra Saxo innata. Aldrovandi Tab. de Zoophytis, No. vii.

with its exploratory feelers, holding it fast. The mouth, or small central cone or protuberance, opened into three ferrated valves, to which some of the feelers kept continually moving from the limpet, using them in the manner of singers; at length being satisfied, it let it go, and by a gradual contraction shut up all its beauties. The limpet looked a little shrivelled, as if it had lost some of its juices, but no lacerations could be discovered by the naked eye.

The Sea-Nettles have their name from the disagreeable tingling they cause in the hand on touching them. They are said to taste like pepper ‡. They were received into the Roman cookery ‡.

## CHAP. XI.

## OF FISHES.

HALES are rare in our feas. A *sperma-ceti*-whale (a) was cast on shore about twenty years ago at *Hauxley*, near *Warkwarth*. It was fifty-four feet long, and thirty-six feet broad; the breadth of the tail sifteen feet; the teeth about forty-two, large, solid, and white, sixed in a double series in the lower jaw; the *sistula* or spout in the neck.

Another of the same kind was found dead at sea, about forty-four years ago, by the fishermen of *Cresswell*, who towed it on shore with their boats; the head and tail in a wasting state; the jaw-bone sixteen feet long; the nostril at this time serving for a spout to a well at *Blackmore-Hall*. This whale affords the true sperma ceti, which is nothing else but the liquid fat, thoroughly refined by art, the head yielding the purest and best, and the greatest quantity \*.

<sup>\*</sup> See the curious and ingenious Essay on the Natural History of Whales, by the Hon. Paul Dudley, Esq; Ph. Tr. No. 387.

- 2. The Grampus, Bottle-nose, or Great Porpess (b), is sometimes observed on the coast. Sixty-three of them came on shore at Shorestone, 29th July, 1734, about noon; fixty of which were between fourteen and nineteen feet long, and the other three about eight feet. They were all alive when they came on shore, and made a hideous noise, but were soon killed by the country people, who removed them one by one, with fix oxen and two horses, and made about ten pounds by their blubber. The same kind of noise was heard in the sea the night before by the shepherds in the fields, when it is supposed they were sensible of their diffress in shoal-water. The maxilla of this large fish are armed with teeth, above and below. It hath a fiftula or fpout in the middle of the head, and three fins. It is a great enemy to the whale, and purfues it with fury. There is fometimes a fierce engagement, for feveral hours, between it and the shark, called Vulpecula, or Sea-Fox; a fish of great agility and subtilty, which watches his rifing to the furface of the water to breathe, and then gives him many a fevere stroke with his tail, with such force and dexterity, that the Cornish call it, The Thresher.
- 3. The lesser Porpess (c) is frequent under the promontories, and in the deep bays, upon the sea-coast; many of them sporting some-

fometimes together on the furface of the waves, rolling and tumbling like a parcel of fwine. Hence it is generally called, A Sea-Swine. It is large and coniform; the fiftula or water-spout in the middle of the head, with fix lesser apertures about the rostrum; the maxilla or jaws wide, furnished with an apparatus of teeth, forty-eight on each fide, standing in a row like little blunt pegs; the tongue dentated at the edges, of an equal breadth to the very extremity, tied down to the bottom of the mouth along the middle. The roftrum is long and muscular, to enable it to get its living by digging up the fand at the bottom of the feat The anguilla de arena, or fand-eel, is its favourite food. Its structure, on diffection, appears very much like that of quadrupeds. The fibrous fat under the skin feems to be designed for the prefervation of the blood in a warm and tepid state, and to detain its finest and subtilest parts from evaporation. Both the phocana and the whale are remarkable for the particular polition of their tails, not flanding erect perpendicularly to the plane of the horizon, but lying parallel to it, to facilitate their afcent to the furface of the water, by a jerk, for respiration, to balance their bodies for fwimming, as the anterior fins do in other fishes, or the hinder legs of quadrupeds.

4. An exotic and fingular-coloured Shark (d), was taken in a falmon-net at the Oftium of the Tweed, a little above the bridge, in September, 1757. It was fix feet long, and of a greenish colour; the mouth armed with teeth, large, and formidable. The

<sup>&</sup>quot;Sunt proculdubio longe plures hujus ordinis pisces in mari occidentali & septentrionali, quorum notitia nos sugit, cum raro capiantur, & mortui solo vulgo observentur & negligantur." Linn. Obs. 1. c.

<sup>(</sup>d) Lamia. Charlet. Pifc. p. 12. n. 7.

fishermen, on first hauling the net, were in rapturous expectation of an extraordinary and unusual draught of salmon, but on drawing it near to the shore, great was their consternation and surprize on the sight of this dangerous creature, which made the water sly about their ears to a prodigious height. It is supposed to have followed the East India sleet to Edenburgh-Frith, and to have directed its course southwards, in forward and eager pursuit after the salmon. When the Shark is thus intent upon his prey, his teeth are erect, but at other times they lie slat. Two or three pilot-sishes are for the most part with him, in the quality of Gustatores, commonly tasting his food before him. He has also some other small sishes which bear him company, with transverse folds on the head and back, clinging close to his sides, waiting for such morfels as he shall let fall from his mouth.

5. That remarkable fish, the Rana Piscatrix, or Frog-Fish, Toad-Fish, or Sea-Devil (e), was found alive on the shore near Cresswell, deferted by the tides, in the beginning of the year 1763. It was four feet and a half long. It is a fish of a terrible aspect; the head more than equal in size to the rest of the body, the mouth bearded, exceedingly wide; a triple irregular series of teeth in the jaws, fauces, and root of the tongue, turned inwards for holding its prey. The eyes are on the top of the head, very large. Near the extremity of the rostrum, are two long, slender bodies, like tentacula; also three short ones on the back, and many short sleshy pinnules on the sides. With these it is said to explore and allure its prey, by vibrating them at pleasure. It hath some protuberant appendages about the rostrum, the eyes, and other parts of the head. It hath two ventral fins, standing near

<sup>(</sup>e) Rana Piscatrix. Charlet. Pisc. p. 11. n. 4. cum Icone optima & dissectione, p. 74. Will. Pisc. p. 85. t. E. 1. Salv. Hist. Aquat. p. 140. Dale. Harw. App. p. 422. n. 4.

together, each confifting of five rays, thick, fleshy, and of a pale reddish colour. The tail is large, not forked at the end. The viscera of this fish were taken out, and the case distended and dried, to shew its interior structure; in which state it makes a most extraordinary and uncommon appearance: the dreadful apparatus of teeth, the large gills, and the transverse bone-like cartilages, being all in view, and wonderful to the beholder. It was presented to me, together with a small one, by my respectful friend, Edward Cook, of Blackmore-Hall, Esq; who assures me it is not unfrequent on that part of the coast.

6. The Wolf-Fish is sometimes taken by the fishermen of Holy-Island (f). It is a singular made fish. The head is large and depressed; the mouth prodigiously wide; a vast number of large and strong teeth in the jaws, on the palate, and deep in the fauces. The eyes are on the top of the head, large and prominent, of a sierce aspect. The nostrils have each a double aperture. The body is of a compressed shape, of a greyish-brown colour, elegantly variegated with black on the sides, transversely. In handling it is as subricous and slippery as an eel. It hath no ventral sins. The back-sin is very long, extending almost to the tail; the pectoral sins large and rounded; the pinna ani long and low; the tail of a square sigure. It is a bold voracious sish, destroying in an instant what it lays hold on with its frightful

<sup>(</sup>f) Lupus marinus. Charlet. Pifc. p. 31. n. 2. sequenti observatione.

<sup>&</sup>quot;Mire vorax mordaxque animal est, & dentibus suis terribile. Anchoram enim si præ"hendat mordicus, sonum edit & strepitum, & vestigia conspicua relinquit. Ex dentibus

<sup>&</sup>quot; ejus molaribus fingere solent Gemmarii fraudulenti Lapides Busonios, & magno pretio

<sup>&</sup>quot; vendere."

teeth; which, when found fossil, make the gems called Lapides Buffonii \*.

- 7. The Lump-Fish, Sea-Owl, or Cockpaddle (g), is frequent on the coast, especially at Cresswell and Holy-Island. It is a well tasted sish, but of a clumsey sigure. The head and mouth are moderately large; the eyes small, and covered with a cuticle; the jaws and fauces armed with a great number of small sharp teeth. The back is elevated, the belly stat. It hath a triple series of restlex, sharp, prickles on the sides, and as many on the back. It is of a beautiful colour, variegated with black, a pale red and whitish. The ventral sins are connected at the ends, and are of a funnel-like shape; by the help of which it holds itself fast in storms to the bottom of the sea, and to rocks. There is an anatomy of it by Dr. Tyson in Willughby's Ichthyology.
- 8. We have also the Pogge (h), a singular shaped little sish, about six inches long; of an octangular sigure to the hinder end of the back-sin, and from thence to the tail hexangular. The whole body is covered with bone-like scales, which being raised or elevated in the middle through the whole length, give it those peculiar angulated sigures.

- 9. The Cat-Fish (i), so called from the likeness of its whiskers upon the upper lip to those of a cat, is sometimes taken by our fishermen. The fins are poisonous.
- 10. The *Dracunculus*, or *Sea-Dragon* (k), is frequently taken. It is of an irregular and uncomely form, armed with fpines, the fides of a yellowish-olive colour, streaked with black, cross-ways.
- by the fishermen of North Shields. The head is large, and somewhat compressed; the eyes situated near each other at the top of it; the iris a bright yellow; a large and robust spine near the operculum of the gills; the dorsal sins poisonous, raised and concealed at pleasure, in a deep furrow, by which it is enabled to do the greater mischief.
- 12. One of those remarkable fishes, called the Baffe(m), approaching the figure of a falmon, of a deep blackish colour on the back, and of a filvery white on the belly, was taken near Cresswell, and brought to me. It is a firm well-tasted fish.

- 13. At the oftium of the river Tyne, the Sturgeon (n) has been fometimes taken.
- 14. That valuable fish, the Assellus major, or Cod-Fish (o), is taken in great quantities in our seas. It preys upon young crabs, lob-sters, herrings, &c. to which it is very destructive.
- 15. The Ling (p), a more delicate taked fish than the former, and more valued, is frequently taken. The annual exports of both to London are usually very considerable, besides our homeconsumption.
- 16. The Haddock (q), a most desirable sish, is taken in such abundance, as to furnish all tables, and to reward the toil of the hardy sishermen.

17. The

- 17. The Whiting (r), a foft, but well tasted fish, is less plentiful than the Haddock. There are two small bones in the head much used in making artificial flowers, and their pendulous narrow foliage.
- 18. Whiting-Pout (s) is often taken. It is lefs effected than the whiting. It is a fhort, broad fifh, rarely growing longer than nine inches, or broader than three.
- 19. The Coal-Fish (t) is taken plentifully near the sea-rocks. It is nearly of the shape and size of a Whiting, a dusky yellow on a black ground, in an elegant variegation; the mouth large, and armed with numerous white teeth; the lateral line straight, very broad, and white.
- 20. The Whiting-Pollack (u) is taken in abundance with the former, from eight to thirteen inches; the mouth also large, and

armed

armed with numerous sharp teeth; the lateral line of a dusky hue, broad and crooked. They are both foft, and of a watry taste. They afford good diversion with a hook and line, taking a bait greedily; the angler either sitting or standing upon a rock, on a serene cloudy day, usually taking great numbers, in the space of a few hours.

- 21. That beautiful and admired fish, the Mackrel (v), is sometimes taken, but not often. In the year 1762, which was a remarkable dry summer, even to the destruction of our herbage, we had them pretty plentifully in all our better markets.
- 22. The valuable and justly esteemed fish, the *Herring* (w), is an annual visitant of our northern coast, and is sometimes taken in great numbers, but not enough for export.
- 23. We have the *Turbot* (x), the most firm and delicate tasted fish of all the flat cartilaginous species, with which not only our own, but many of the *London*-tables, are often supplied.
- (v) Scomber. Charlet. Pisc. p. 27. n. 4. Schonef. Icht. p. 66. Will. Pisc. p. 181. Tab. M. 111. Raj. Syn. Pisc. p. 58. Scombrus. Salv. Piso. p. 241. t. 239. - 29. The Thornback (d) is taken in great abundance. The fmall younger fort, usually called Maids, are most esteemed.
- 30. The admired fish, the Gar-fish, or Needle-fish (e) is taken plentifully near Budle. Its retirement is in the fands at ebb-tides. On their reflux it swims about with great alertness, regaling it-felf not only with the sweets of liberty, but with food. The flesh is extremely white, and of a delicate taste, like the Mackrell's. The bones are green. Hence it is called by our fishermen, the Green Bone.
- g1. The Sand-Eel (f) is taken in great abundance in the feafands; the largest at Budle, and near Craster. It leads the same kind of life as the Gar-fish, and shews as much joy on the returning tides.

- 32. In high tides, in the latter end of May and beginning of June, the Cuttle-Fish (g), is frequently brought on shore with the sea-weeds. It is furnished with ten horns, with which it rows itself in the water, as with oars; and when in any danger it escapes by discolouring the water with an inky liquor. Hence it is called by some the ink-sish; and from one half of it being invested with a membrane, like a leg within a stocking, it is called by others, the Hose or Stocking-Fish. Its substance seems tobe a kind of pulp. It has only one bone, and that in the back; used by silversmiths in burnishing plate. It has spots on the back, somewhat resembling those of a trout.
- 33. Of our Fresh-Water-Fishes, the Salmon (h) is the most valuable. It is so plentiful in the Tweed, that the annual export of that single article from Berwick is very considerable. It is frequent in all our other rivers towards the sea, in the Aln, Coquet, and Tyne, but the Tweed-salmon has the preference. It is recorded of an alderman at Newcastle, Francis Anderson, Esq; that dropping his gold-seal-ring from his singer into the Tyne, as he was leaning over the bridge, it was found in the belly of a Salmon, bought in the market by one of his own servants. It is now in the possession of Mr. Edward Anderson, his descendant, a merchant of that

corporation. The impression is that of Solomon and the queen of Sheba. On the inside, just under the signet, the alderman had the effigies of a salmon engraved, with the initial letters of his name on each side, as a memorial of so extraordinary an accident, similar to what is told of Polycrates, king of Samos, by Herodotus \*.

- 34. The Salmon-Trout (i) is taken in great plenty in the fame rivers with the falmon.
- 35. The Whitling-Tront (k), of a long and compressed form, is taken in the Till and Tweed from ten to twenty inches. It is the most admired of all the trout-species, the slesh as red as a Salmon's.
- 36. The Aller-Trout (1), usually large and well grown, is frequent in the deep holes of our retired and shady brooks, under the roots of the Aller, or Alder-tree, from which it has its name.
- 37. There is a finall trout in our alpine rivulets, usually called, The Rackrider (m), of great esteem; the steff white, but exceed-

those that feed in muddy waters, but better tasted, and of a brighter colour. Under its exterior lubricous coat, it has a scaly vestment, very curious, constituted of oblong and round balls, some reticulated, and finely pencilled, but so small as to require to be viewed with a microscope.

- 46. The Lamprey-Eel (v) is frequently taken in our larger rivers towards the fea. It has a feries of feven roundish apertures on each side of the head, downwards, which are of the same use as gills in other fishes.
- 1. Of our marine crustaceous Shell-Fishes, the most valuable is the Lobster (w). It is taken in such plenty, that the annual export usually amounts from 1200 l. to 1500 l. of those that are taken between Newbiggen and Newton by the sea, exclusive of such as are taken at Holy-Island, which annually amount to a considerable sum; as I am assured by John Cresswell, of Cresswell, Esq; who has for some years past paid those sums by the order of a London-sishmonger, Mr. Kittermaster, on whose account all the most valuable sea-sishes on this coast are taken and shipped off for London, which makes them often difficult to be had at home, and rarities at our tables.

- 2. The Sea-Crab (x) is taken in great abundance; many of them very large.
- 3. The great fubglobose Echinus, or Sea-Egg (y), is frequently taken with the fish in it by the Lobster fishermen of Newton, near Embleton. The shells are of different colours; some red, and others purple, in lighter and deeper shades. I had one of a sine purple, with white striæ on the joints, and so large as to hold near a quart of water. The spines are white, slender, and short, not above half a singer's length. The progressive motion of the fish is by turning or rolling itself upon its spines in the ocean. It is no sooner dead, or out of water for a small space, than its spiny armour drops off. It was a great favourite at table among the antients, and was called The Ovum, or Egg. The sless with pepper and vinegar, at the time of the full moon, when it is turgid, and esteemed a delicacy.
- 4. The depressed cordate *Echinus*, or *Sea-Egg* (z), is very plentiful on the coast near *Alumouth* and *Holy-Island*. On the south side of the river at *Alumouth*, great numbers of empty shells are brought on shore by the tides in tempestuous weather, mostly about *Michaelmas*; some of them with their short slender set or bristles on;

others polished by the sea, of a bright white, with a double series of small apertures, and elegant striæ and papillæ.

The Echini keep the deep waters, near the shores \*.

1. Of the barder marine Shell-Fishes, the most valuable is the Oyster; the common fort; usually large, and of an excellent taste; such as would have pleased the nicest Roman palate.

Circeis nata forent, an Lucrinum ad Saxum, Rutupinoque edita Fundo Ostrea.— Juv. Sat. iv.

They are on a bank belonging to the Right Honourable the Earl of Tankerville.

- 2. The fmall Rock-Oyster (a), a delicate tasted oyster, is frequent among our northern sea-rocks.
- 3. The common Pectunculus, or Cockle (b), is found in great abundance in the mud and fands at Budle, near Belford, very large, and of an excellent taste. The shells are of various colours, a pale blue, a deep blue, with white bands or sillets; the white, with blue sillets, tinged with a sea-green; others with orange-sillets on a bright white ground, in lighter and deeper shades. Great numbers of them may be gathered on Ross-links, polished by the sea.

  - (a) Ostrea parva saxatilis. List. Angl. t. 4. f. 26.

<sup>(</sup>b) Id. t. 5. f. 34.

- 4. The large, high-beaked Pectunculus, or Cockle (c), is not unfrequent in the fame fands.
- of the river Coquet, and on the fea-shore, among the sea-weeds, after high tides; where I have frequently gathered them, with the sish in them. The shell is white, tender, and pellucid; the sish like that of a cockle, and well tasted.
- 6. The thick, white, striated Chama (e), is frequent on Ross-links. I have observed it also on the sea-shore, near Embleton, and Wark-worth. The strike are transverse and irregular; the interior extreme margin tinged with blue.
- 7. The Sea-Muscle (f) is plentiful on the sea-rocks near Alumouth, and many other places. The fish pickled is esteemed at some tables preferable to a pickled oyster. Our sishermen use it to bait their hooks. Some of the shells are streaked with black on a light olive-ground.
- 8. The pearl-coloured Solen (g) is plentiful in the fands at Budle, and may be taken without any trouble in the night with a lan-
- (c) Pectunculus maximus, at minus concavus; plurimis minutioribus et parum eminentibus striis donatus, rostro acuto, minusque incurvata. List. Angl. p. 187. t. 5. f. 32.

- (g) Concha fusca, longissima, angustissimaque, musculo ad cardinem nigro; quibusdam Solen dicta. List. Angl. p. 192. t. 5. f. 37. Append. p. 34, 35.

thorn and a candle, after the high spring-tides, about the full moon, especially in February and March, when they may be easily seen with one end erect above the fands. The shells are usually from fix to seven inches and a half long, and one broad; open at both ends; the exterior cuticula, or covering, when first taken, brown, with a tinge of yellow, which shrivels and falls off after the fish is dead, and exposed to the sun. This sish is a tethys, cartilagenous, and glabiated, with small auricles, or ears, and four tentacula; white, or of a cream-colour; in great esteem at the table in some places, under proper culinary management, but only used with us as a bait.

- 9. The orange and white Solen is found in the fame fands. It is in all respects like the last, except the colour, which is a deep orange and white, in transverse fillets, in alternate variegations.
- 10. The long and broad Conch-Shell, with alternate fillets of yellow, carmine and white, in a beautiful variegation (b), is frequent on the shore near Ross-links, with the common yellow ones.
- 11. The long and broad Conch, with yellow, dark brown, and light and deep blue fillets, is found on the same shore. The fish is much esteemed in some places.
- 12. The large, round, thick, and tawney Conch (i), is frequent on the whole coast. The investient cuticula is a black-tawney, which
- (h) Concha tenuis, longa, lataque, in mellis cardinibus cavitate quadam pyriformi infignita. Id. t. 4. f. 19. Hen-Fish. Hantoniens.

thrivels and falls off after it has been for some time exposed to the sun and the weather, and shews its interior chesnut-hue. They may be gathered from the size of a small cockle to that of a pretty large scallop. The sish is well tasted. The judicious and admired Mantuan, in his System of Husbandry, recommends the putting conch-shells, rough and squalid, under the roots of new planted trees, to drain the water from them. They also answer a higher use. Their alcaline salts destroy the acidities of the earth, forward vegetation, warm and strengthen the sibres, give a fine bark, and vigour and health to trees. He might have this advantage in his eye, though he does not mention it.

Squalentes infide Conchas.

VIRG. Geo. 2. v. 348.

13. The white, very-beaked, striated Conch (k), is frequent on the shore near Ross-links. The shell is strong and thick; the strike deep, transverse, and irregular; the interior extreme margin serrated.

14. The thick Orange and white striated Conch is sometimes obferved and gathered on the same shore. The surrows are white, transverse, and horizontal, parallel to the margin; the ridges a deep orange, with intermediate smaller ones of a bright white, very beautiful.

15, 16, 17. The small, smooth Conch with red and white Fillets, and the small smooth Conch with bright yellow and white Fillets, are frequent on the shores near Druridge and Holy-Island; also the small, smooth, white Conch, tinged with red. They are strong and thick shells for their size, not bigger than a small bean.

<sup>(</sup>k) Curvirostrum Sulcis sive Striis transversis profunde infignitum.

18, 19, 20. The Tellina with Purple, yellow, and white Fillets, and the Rose-coloured Tellina with white Fillets, also the white Tellina with Pearl-coloured Fillets, are frequent on the shores near Wark-worth, Embleton, Ross-Links, and Holy-Island. The shells have a high natural polish; those of the two last extremely light and tender, finely formed for making small artificial flowers.

I have gathered most of these Bivalve shells with the sishem. They inhumate themselves in the Sands at ebb-tides, and on their reslux open their valves for food and pleasure.

themselves in Stones, and live a recluse hermit-kind of life, are frequently brought on shore in high spring-tides and storms, both with and without their stony habitations. Some of the stones are large, ponderous, very hard, and of a livid colour. I have observed great numbers of them among the rocks at Hartley, Blyth, and Almouth; with both the large, white, striated, and the small and slender, Pholades, in them, and other kinds. The Italians call the stones, Balle di Sasso, and the sish, Ballare, or Dattyli de Mare. The sishermen of Ancona take the stones up at sea, where they find them in great plenty, and keep them in the harbour, to have the sish ready for the table. It is of a grateful taste, and valued next to a scallop, or an oyster\*.

Pectinated Bivalves, or Scallops, with the fifth in them, are rarely observed on our coast. Single valves, both with equal and unequal ears, and others with ears so short, as hardly to be perceivable, are sometimes found on the shores.

<sup>\*</sup> Ray's Topogr. Observ. Vol. 1. p. 323.

- 22. I met with the white-ribbed Petten or Scallop, fpotted with red, on the shore of Holy-Island. It is two inches and a half long, and as many broad.
- 23. On the shore at Ross-Links, I found the white and purple ribbed Pecton; two inches long, and as many broad, beautifully marbled and variegated with purple and white (1).
- 24. In a Creek, on the fouth fide of the Oftium of the river Aln,. I met with the brown echinated Scallop an inch and three quarters long, and an inch and an half broad (m).
- 25. From the same place, I had the Snow-white and bright red Petten, with short ears; an inch and a quarter long, and somewhat above an inch broad.
- 26. The light yellow and purple ribbed Petten is frequent on the shore near Warkworth. It is of a beautiful yellow, elegantly marbled with a deep purple.
- 27, 28, 29. The deep, gloss, purple Pecten, the bright red echinated Pecten, the pale red Pecten, variegated with purple and white, are frequent on the same shore.
- 30. From the shore at Ross-Links, I met with a valve of the white ribbed Pectunculus, or Cockle; a strong and beautiful shell, with a double series of longitudical striæ; thirteen striæ very
- (1) Pecten altis Striis albo-purpureis transverse variegatis infiguis.—Berlase's Chrimall. p. 278. t. 28. f. 22.
  - (m) Pectunculus echinatus. Ibid. f. 19.

deep, and as many small narrow ones down the middle of each ridge; three other small ones crossing them, circular and wavy.

31, 32, 33. The common Univalve Shell-Fishes, the Nerite (n), the small Turbines (o), the Patella or the Mammillares (p), are numerous upon our fhores; the two former well tafted and wholefome, when boiled, and frequently fold for the table on the more fouthern coasts; the other only used by the fishermen to bait their hooks. The Nerit-shells are some of them a pale red, and others yellow. Some of the Turbines are white, flriated with purple; and others a dark brown, striated with white; the apices of fome fhort, and obtuse; others acuminated. The Patella are of various fizes, shapes, and colours; some flattish, some hightopped or coniform; fome blue and pellucid on the exterior furface, with fine capillary Radii from the vertex to the margin, and of a pearl-colour within; some with acute rays, filleted without with blue and white alternately, and of a gloffy Sattinwhite within; fome white, with red and purple fillets, dotted; fome red and orange externally, and white within; fome with more fharp and acute Radii, with a sharp apex, brown without, and powdered with white; within, friated with blue, yellow, and red; refembling the pips of some beautiful Auriculæ.

34. The *small purple Murex*, *Turbo*, or *Whelk*, yielding a purple *Sanies*, is in great abundance among the fea-rocks. The *British* ladies antiently marked their linen with the purple *Sanies* or juice

<sup>(</sup>n) WINKLES. Hantoniens.

<sup>(0)</sup> WHELKS. Iifdem.

<sup>(</sup>f) Limpers. Pap-Shells. Lift. Angl. p. 195. t. 5. f. 40. Flithers.

found in it, in a white vein next the head of the fish, lying transversely in a cleft or furrow. It is fetched out with the stiff point of a horse-hair pencil, short, and tapering, the shell being first broke, the mouth downward, with a smart stroke of a hammer, on a piece of sirm smooth wood, taking care not to bruise the sish. Our northern historian, Bede, mentions it, in words that express its beauty and duration. There are, says he, on the English shores an abundance of the Cochlea which yield a scarlet dye. Its beautiful tinge neither sades by the heat of the sun, or by the weather, but the older it is, the more rich and elegant \*.

35, 36, 37. The large, thick, Buccinum, or Whelk (q) and the thin wide-mouthed Buccinum, or Whelk (r), with feven volutæ, and transverse wavy striæ, are frequent on the shores near Ross-Links, and Holy-Island; also the narrow-mouthed Buccinum or Whelk, with eight wreaths (s). The Whelk-sish, boiled, or roasted, is hard and sirm, and much esteemed at some tables for its agreeable taste. The Hermet or Soldier-Crab often makes choice of the smaller empty shells for its retreat and habitation, closing the aperture with its forcipated claw. The grey, narrow-mouthed Balanus, a multivalve, is often found upon them, many together; the fish in it called a Triton, the body of it oblong, the rostrum spiral at

<sup>\*</sup> Sunt Cochleæ fatis superque abundantes, quibus tinctura coccinei coloris conficitur. Cujus rubor pulcherrimus nullo unquam solis ardore, nulla valet pluviarum injuria pallescere; sed quo vetustior, eo solet esse vetustior. Hist. Eccles. Edit. Opt. L. 1. C. 1. p. 277.

<sup>(</sup>s) Buccinum angustius, tenuiter, admodum striatum, octo minimum spirarum.—Ibid. Fig. 4.

the mouth, with fourteen tentacula, twelve of them cheliform (t). Almost all the stones on the fouth side of the river at Almmouth are covered with this Balanus, also many of the Patella on the shores.

- 38. Of the *small Trochus*, or striated papillaceous top-shell, with five *Volutæ* (u), I have gathered a quart or two at a time, with the fishes in them, at ebb-tides among the sea-rocks, near *Embleton*. The investient *Cuticula* of the shell is brown, and very rough. When polished by the collision of the sands and tides; it is of a beautiful pearl-colour, with brown striæ, transverse, and wavy.
- 39, 40, 41. The Trochus with fix Volutæ, and an acuminated apex (v); the small striated Nun or Venus-Shell (w); and the very small depressed orbicular Cochlea, are frequently brought on shore empty; the first most rare and most beautiful, with red spots on a pearl-coloured ground; the second often gathered on the shores near Embleton, and at Holy-Island; the last, with only one wreath, is found in great numbers on the soliage of submarine plants.

The fresh-water shell-sishes, the Mytuli sluviatiles, or River-Muscles, are plentiful in most of our rivers.

- (t) Balanus cinereus, velut è fenis laminis striatis compositus, ipso vertice altera testa, bisida, rhomboide occluso. List. Angl. p. 196. t. 5. f. 41. Balanus ore contracto cinereus. Borlase's Cornwall, p. 278. t. 28. f. 29, 30.

- (w) Concha Veneris minima nullis maculis infignita. Borlase's Cornwall, p. 277. t. 28. f. 13.

- 42. Of the Mytulus major margaratiferus, or great Pearl-Muscle (x). I have gathered very large ones in the Tweed, the Aln, and North and South Tyne; fome of those of the Tweed and the Tyne wrinkled. twifted, or bunched, which are noted for having the best pearls, but it was never my fortune, to find any in them. The British pearl was a lure for the Roman eagle, and was esteemed by Julius Cafar as a reward for his victories \*. Venerable Bede, our countryman, takes notice of them, and gives them high encomiums for their beauty: their colours various; a maiden-blush, purple, and fome emulating a gem, the glowing Jacinth, but most of them white †. Their origin is ascribed to the same cause as the stone in animals, from some of which stones have been taken like feed-pearl, fmooth and shining like burnished gold; the external coat preferving its brightness in fpirit of vinegar, and as difficult to be diffolved in it as true pearls ‡.
- 43. The *fmall Muscle* (y) is frequent with the former in the same rivers; the shells broad and slender.
- 44. The long flender Muscle (z) is found in great abundance in the Tyne and the Aln, where I have often observed it, with its valves open, near the banks, on a fine funny day (a)

45. The *small round Muscle* (b) is less frequent than the rest. I found some of them in a piece of water at *Brome-Haugh*, near *Chipchace*, with the *depressed orbiculated Cochlea*. It is of a globose figure, of the fize of a small hazel-nut, and of a dark olive hue.

The exterior coat of the *Mytuli*, and other shells, may be easily taken off by boiling in any strong *Lixivium*, or lye, and their interior beauty seen in all their pearly splendor, sit for either curious slower, or grotto-works, or for medical uses. The interior pearly substance of the *Mytuli*, reduced to powder, is of equal esteem in medicine with crabs eyes or pearls.

<sup>(</sup>b) Id. App. t. 1. f. 5.

## CHAP. XII.

## OF QUADRUPEDS.

The most valuable of all our domestic animals are our sheep. Our mountains and hills are almost covered with them. The largest, with the finest wool, are on the hills of Floddon, and by the rivers Till, and Tweed; a species without horns, of the middle size, between those of Scaland and Yorkshire. The Flemish manufacturers always preferred our English wool to the foreign; and our ancestors provided wise and good laws against its exportation, and coming into their hands. King Edward III. in the second year of his reign, procured an act to be passed in his parliament at Westminster, that it should be all made into cloath at home, that manufacturers should be invited from abroad, proper places assigned them to live and work in, with great privileges and immunities, and good wages and salaries allowed them till they were properly settled, in a prosperous thriving way \*.

Notwithstanding this wife and good law, foreigners found means to have our wool from our northern borders, probably by the agency of the *Flemish* merchants then settled at *Berwick* upon *Tweed*. It is recorded to have been excellent combingwool. In later times, some good estates are said to have been got by sending it abroad.

Lewis XIV. the glory of France, was the first distinguished patron and encourager of the woolen trade in that kingdom.

The flice fixed upon for a cloath-manufacture was Languedoc, where it was carried on with vigour, by a royal fund established for that purpose, after the example of our great King Edward III. Cloath, in Lewis's time, was made from about 9 s. to 10 s. a French ell. It has fince that period been made at that and other places in France of a greater fineness, from 10 s. to 14 s. an ell, and upwards; much like our Gloucestershire-cloaths, 7 quarters wide.

Various trials and experiments have been made both in France and Flanders to have wool as fine and as good as our's, for the fabric of their cloaths and ftuffs. All their efforts have proved ineffectual, owing, as is thought, to the herbage, and the night-air in winter. The wool of English sheep carried over, and fed upon their best herbage, has been better the first year, but afterwards grew worse and worse, like their own. This was tried on the best ground between Dunkirk, and Graveling, in France, and by a nobleman \* at Belisle, in Flanders, twenty miles from Mentz. The only way in Flanders of keeping the wool of their own sheep from degenerating, is by housing them in the night, in winter. The shepherd has a moveable house, drawn at pleasure on two wheels after the sheep, being their companion, with his little dog, night and day.

Those people then, and other foreigners, having no fine combing-wool of their own, how come they by it for their numerous manufactures, which cannot be carried on without it? This question is fittest to be resolved by those, in whose power alone it is to provide a remedy, and to secure to Britain this its indigenous treasure, preferable to all the mines of India, which, if

<sup>\*</sup> Prince Deloign.

enjoyed in its full extent, would keep our artificers in the various branches of the woolen trade from leaving with regret their mother-country for bread, and feeking it among strangers, our natural enemies.

Great improvements have been made of late years in the breed of our sheep, by changing the males, fowing grass-feeds, &c. Combing-wool is now to be had in most parts of the country, very good, long, and foft, fit to make all forts of the finer stuffs and hofe; also some short, and very sine, sit for making cloath, commonly used with Spanish wool, to strengthen the chain or warp. It is generally bought for the woolen manufactures at Leeds and Halifax, in Yorkshire. It must be acknowledged, indeed, that the best of our wool is inferior to some in Leicestersbire, and in the fouth marshes of Lincolnshire, which is reputed the longest and best combing-wool in England, remarkably fine and foft, of a beautiful gloss, chiefly used in making Norwich-crapes, bombazines, &c. The coarse wool of our own growth is usually made into bays for export, of which there has been for fometime a manufacture at Hexham, and another lately established at Haltwefel, in a flourishing prosperous way.

Confiderable quantities both of our coarfer and finer wool is kept at home by private families for their own cloathing, of their own manufacture; who value it the more for being of their own growth and fabric. Weavers are in few places more plentiful than here. Some of them are very ingenious, making carpets of an exceeding good pattern and figure, also linens of all kinds, not inferior to the *Scotch* or *Irish*. They are kept in employ by the same families, whose whole cloathing is of their own manufacture, woolen and linen, spinning both themselves.

Some perfons of better fashion employ their leisure in spinning woolen-stuffs for the use of their little offspring, on a small machine of brass, invented by a mechanic on the *Scotch* borders; of a simple construction, consisting only of a wheel, a handle to turn it round, and two arms to six it to the breast.

Our Oxen, in the north-east, and east part of the county, are remarkable for being large and well-made, and are usually sold for a great price.

Horses of strength and size for service were rare in the north till the year 1435, when a sine sort were imported from Hungary into Scotland, by the order of the Scotch king, the accomplished James I. educated at the English court; whereby the English borderers were furnished with a martial and handsome race, Equi volucres; their horses before being only like our alpine hobbies, Segnipedes, not rouzed by the warrior's or the hunter's horn.

The most beautiful of all our wild gregarious animals are the Red-Deer; become very scarce by the eager pursuit of sportsmen, and others, after them; but seldom seen, except in the forest of Knares-dale, where I have seen about five or six in company, never more. The moment they behold any of the human species, they are struck with terror, and sly like lightning to some secure and experienced retreat for refuge. One of them commonly stands centinel, and alarms the rest on the approach of any danger. A fawn sometimes has the missortune of being taken by surprize in its slumbers, and by kind usage becomes tame and familiar.

By the good laws made for the prefervation of these fine creatures by our ancestors, they lived in a state of security and ease. The dogs were reftrained from diffurbing them, by being expedated. For neglecting this excision, the men of Northumberland were fined, 14 K. Henry II. They were not excused doing this office till the general disforefling of chaces and parks, 9 K. Henry III. 1225. That king, in the 30th year of his reign, 1246, caufed fevere laws to be enacted for the punishment of robbers of forests, parks, and warrens; making it imprisonment for a year and a day, besides the forfeiture of three years value of the convict's estate, two parts to be paid to the king, and one to the person injured, allowing a fmall portion for the prisoner's support, not to be released under the number of twelve sureties for his future honefty, all answerable for his conduct. Deer being stolen, an inquisition was made by the king's writ, and if any one was taken in the act without it, the penalties were the fame, and if killed in the purfuit, there was no law, appeal, or remedy, for his death ‡.

The forests of antient note in this county, were

The forest of Cheviot.

The forest of Rothbury.

The forest of Reed's-dale.

The forest of Eresdon, near Long Horsley.

Thefe

These forests were all antiently stored with red deer. There were near 6000 head of deer, red, roe, and fallow, in the forests and parks of the right honourable the Earl of Northumberland, in the northern counties, 4 Henry VIII. 1512; according to an account given by his Majesty's commissioners; and at the same time there were red deer in his Lordship's forest of Rothbury.

In the park of the right honourable the Earl of Tankerville, at Chillingham, there is a species of wild white cattle, of a diminutive size; said to have been first brought from the Highlands of Scotland, but at what particular time cannot be remembered. A female, with a calf at her foot, is not to be approached without danger. No sooner are people seen in the park, than fired with jealousy for the safety of her little one, she runs with terror and destruction in her looks to meet them, and the rest of the herd sly to her assistance, with the same wrathful countenances, threatening vengeance to the forward intruders. When one of them is killed for the table, it is usually with a gun by surprize, as the Americans kill their wild bulls and cows on the continent; there being no other safe way of doing it; the whole troop on the least alarm coming to the defence and rescue of an injured companion, in a bold and irregular charge.

Hares with us have been as plentiful as in most counties, but they are like to be as scarce as the admired birds of our heaths and mountains, the Gor and Grey; unless our young sportsmen would have more regard to their preservation, and their own pleasure, and not hunt them down annually, like wolves and bears, to be extirpated without mercy. The consideration of their own healths, promoted by the exercise of the chace, should prevail with them, methinks, prudently to save, and not in a

preci-

precipitate fury of defire deftroy an useful and innocent race of beings, intended by providence to give us both food and pleafure, and some part of our ornamentaal and necessary cloathing, for the pitiful and brutal ambition only of boasting among their companions of their killing their twenty, their thirty, and their forty brace, in a season. Savage and inhuman butchery! Away with it from Northumberland. Let posterity enjoy the same blessings, so contributive to health, as our foresathers have done, with moderation.

The Badger, which has various names affigned it (a), is frequent in the woods, and by the fides of rivers, in our alpine vales. It is a fierce creature in its own defence, but otherwife is very harmless. It provides itself a subterrene dwelling, and lives upon infects, reptiles, and the smaller tribes of wild animals. It lives peaceably and retired in the neighbourhood of tame ones, and for that reason is seldom disturbed, except by the young people for the fake of making trial of its courage with fome of their house-dogs of noted ferocity, but some of them often have occasion to repent of the experiment, losing perhaps a favourite or a valuable dog or two in the combat before it is killed, or made to fubmit; and fometimes one of their sportive company receiving a terrible wound in the leg by a bite of the incenfed and injured creature, which usually strikes to the bone with its obtuse, striated teeth, with difficulty to be removed, but by its death. It is of the fize, and pretty much of the shape,

<sup>(</sup>a) Melef. Gefn. quadr. p. 686. Taxus. Charlet. quadr. p. 18. n. 6. Taxus f. Melef. Raj. quadr. p. 185. Meles unguibus anticis longiffimis. Linn. Syst. Nat. 37. Faun. Suec. p. 6. n. 15.

of some of our shepherd's dogs, small; its cheeks tumid, owing to the strong muscles about its mouth, which give it a power to bite so terribly; its ears short and round; its natural cloathing a coarse bristly hair, of a mixed colour, chiefly a dark grey, except the head, which from the crown down the face has a broad stripe of white, and below that another of black, extended farther than the eyes, nearly to the neck, with a whitish border underneath, which makes the head-attire very comely and agreeable.

The Marten (b) is another of our mountain and wood-inhabitants, near houses. It lives upon birds, mice and other small animals. The late humane and much esteemed Edward Charleton, of Reeds-mouth, Esq; had a young one, taken in his neighbourhood, which by kind treatment grew as tame and familiar as his other house-animals, and continued with him two years, brisk and lively, till he parted with it to a friend. It is much esteemed for its fine fur, a deep brown, with a shade of black, bright and glossy. For shape it is as long, but slenderer, than one of our common house-cats, with shorter legs, a little peaked head, long hazel-eyes, short ears, and whiskers at the mouth; the tail as long as the whole body, very bushy, with long, thick hair; the throat whitish.

The Putorius, or Pole-Cat (c), makes its residence in stony hillocks, thickets, and furz, near villages and farm-houses. It is

ufually

<sup>(</sup>b) Martes. Gefn. quadr. p. 151. Charlet. quadr. p. 20. n. 6. Martes aliis Foyna. Raj. quadr. p. 200. Muftela fulvo-nigricans, gula pallida. Linn. Faun. Suec. p. 3. n. 7. MARTEN. MARTERN. Charlet. l. c.

usually called, The Fou'mart, i. e. The Foul-mart, from its intolerable scent; owing to a sætid matter, formed in two glands, near the Anus. Its savourite sood is small birds, and poultry, or their eggs, when it can get at them, and when it cannot, is content to make a meal of mice, and other small animals that fall in its way, but commonly is too successful in its thievish adventures in farm-yards. It is less than the Marten, and its fur of little value.

The Ermine, or White Weafel (d), is not unfrequently feen in winter, in our alpine vales, near houses, and farm-yards. It feeds upon mice, and lives in luxury when it can meet with the eggs of poultry. When it appears abroad, it is said to presage snow. On the authority and observation of the judicious Dr. Richardson, of Bierley, in Yorkshire, it is affirmed to change its colour from brown to white about the beginning of November, and from white to brown in the beginning of March. I have seen it before snow-storms in the middle of winter. Its sur-cloathing was then snow-white, glossy, and beautiful; for which it is much valued.

Besides these animals, there are two others of an amphibeous nature, living at pleasure on land, or in the water, the *Otter*, and *Sea-Calf*, both in great abundance.

The Otter (e) has its habitation under-ground, like the Beaver, which it somewhat resembles, on the shady banks of our larger

rivers, in which, and in our alpine lakes, it makes great destruction of the more valuable sishes, living in luxury, and like a glutton, on salmon, pike, and trout, feeding often only on the shoulders of the salmon, and leaving the rest for less dainty palates. In the deep waters it pursues them with a surprising celerity, and with an almost never-sailing success. It is a creature of a grim aspect, having large and sierce eyes, and whiskers between the nose and mouth; the ears short and round, not in the upper part of the forehead, as in other animals, but on the consines of the neck; the legs short and strong; the feet broad, and connected by a membrane; a sharp claw in each toe; the tail long, and very bushy; the general cloathing of the fur a chesnut-brown, with a slight tinct of grey, pretty glossy.

The fea-calf (f) in the warm fummer-months often leaves the fea to fleep upon the fea-rocks at the Farn-islands, and other rocks near Berwick upon Tweed, where they are often killed for the fake of their skins for horse-furniture, and other uses. To sleep in security, and to prevent danger by surprize, one of them usually stands centinel to give the rest notice, and if attacked, defend themselves with an extraordinary courage, casting stones by the help of their hinder-legs with a surprizing violence, and sometimes at a great distance, upon the affailants. Being in less fear of women than men, they often fall by the hands of men attired like women. There is one very great peculiarity in its structure, being the only viviparous quadruped known to be without exterior ears; its ears being only two small apertures.

## C H A P. XIII.

## OF EMINENT MEN, NATIVES OF NORTHUMBERLAND.

O'educate and form the fouls of men to greatness, to raise in them a passion for glory, for arms, for arts; to inspire them with a resolution to adorn, as well as possess the earth; to provoke them to cast away the fordid love of felf, that grand enemy to virtue, to religion; to our country; I shall lay before them such a portion of Northumberland merit, as has come to my knowledge, whether it be found in great captains, great scholars, great patrons of learning, of trades, and of rural and domestic arts.

And, first, I shall mention such as were great captains. Northumberland-heroism has been much celebrated in our British annals, wherein the inhabitants stand early distinguished under the stile of Armis ferocistini (a), whose leaders were as eminent for their bravery, as their quality; among whom, not the least immortalized in fame, is

Sir John Copeland, of Copeland, by Wooler, and captain of Rox-brough-Castle, in Scotland, stiled by way of eminence in our histo-

ries, The valiant Esquire of Northumberland. In the reign of K. Edzvard III. 1340, he gave the Scots fueh a drubbing, for their deprædations on the borders, as made them both venerate and dread his courage. He was at the battle of Nevil's Cross, near Durham, Oct. 17th, 1346, in the fame reign, where he encountered their valiant King David, and carried him off in triumph from the field to his castle of Roxbrough, attended by only eight of his fervants. Many jewels were found on his royal prisoner, and among the rest, the holy cross of Holyrood-House, which he wore from a vain hope, that it would make him invincible (a). His ranfom cost Scotland 100,000 marks sterling by a treaty, dated 3d October, 1357, at Berwick upon Tweed (b); the furprize of that town by his nephew, Robert Steuart, provoking the English to raise it from 90,000 marks to that fum. Sir John was made a Knight Banneret for this exploit by his fovereign, King Edward; and had 500 l. per annum fettled upon him and his heirs for ever, the patent dated at Eltham, 20th January, 1347 (c).

Famous also are the names of Sir Ralph Grey, of Heton; of Sir William Liste, of Felton; of Thomas Carr, of Etall; and of Sir John Forster, of Bambrough.

Sir Ralph Grey was Knight of the most noble Order of the Garter, taptain of Wark-Castle upon Tweed, and also of the castle of Roxbrough in Scotland, which, in the 4th of K. Henry VI. 1436, he defended against an army of 30,000 resolute Scotchmen, headed by their sove-

<sup>(</sup>c) Hol. Chron. vol 11. p. 376. Rym. Fæd. vol. v. p. 542. Acta Regia, vol. 1. 8vo. p. 309. 1313.

reign K. James I. and conftrained them to raise the siege (d). He afterwards suffered for his loyalty and faithfulness to his pious master after the fatal battle of Hexham-sield, being then captain of Bambrough-Castle (e).

Sir William Lifle was captain of Wark-Caftle in the 5th of K. Henry VIII. 1523, and with a handful of men, forced the Scotch and French, to the number of 2 or 3000, under the command of a French General, the Duke of Albany, who affaulted it with very heavy ordnance, and had entered it, to retire with shame and precipitation, after the loss of 300 men killed, besides such as died of their wounds, and were drowned in the Tweed (f).

Thomas Carr, Efq; was captain of the fame castle, and was one of those valiant gentlemen who, in the 2d of K. Edward VI. 1548, with 200 men, passed in the night to the relief and succour of their countrymen in the town of Haddington, which obliged the enemy to retreat from before it (g).

Sir John Forster was made a Knight Banneret in the 1st of K. Edward VI. 1547, for his valour; and made a fine figure in an engagement with the Scots in 1557, on the borders, near Cheviot, coming off with victory, after receiving some glorious wounds, and having a horse shot under him. By his courage and address he suppressed the rebellion in Northumberland, in the reign of

<sup>(</sup>f) \_\_\_\_\_ p. 881, 882.

Queen Elizabeth, 1569, being then the Lord Warden of the Middle Marches (h).

To these military, let me add those brave naval commanders, Sir Ralph and George Delaval, and Sir Chaloner Ogle.

Sir Ralph, as a branch of the house Delaval, claims a place here. He was named after his father, to whose house General Lesley retired by leave from Cronwell, after the fatal battle of Worcester. He entered very young into the navy, and at the revolution was captain of the York, a third rate man of war. King William, from the great opinion he had of his merit, conferred upon him the honour of knighthood, and made him rear-admiral of the blue, and afterwards vice-admiral of the red, and, as such, had a signal share in the glorious victory over the French off Cape Barsen, May 19th, 1692, so admirably described by himself in the following letter to the Earl of Nottingham, from on board the Royal Sovereign, near Cherbourgh, May 22d, which is the best portrait of him, and shews him to have been both a noble commander, a fine gentleman, and a good Christian.

"I believe it my duty to acquaint you, that on the one and twentieth inftant, admiral Russel having made the fignal for the fleet to cut their cables, I observed the French to be forced from the race of Alderney (where they anchored) to the eastward; and finding, that some of them endeavoured for the bay of Cherbourgh, I stood in for that place, where I found three three-decked ships of the enemies, but so close to the shore, and within fome rocks, that it was not safe for me to attempt them, till I

<sup>(</sup>b) Hel. Chron. vol. 1. p. 361, 397.

" had informed myself of the road; they being hawled into the " fhoal-water, I immediately took my boats, and founded within "gun-shot of them; which they endeavoured to prevent by fir-"ing at us. And, that no time might be loft, I went immedi-"ately on board The St. Albans, where, for the encouragement " of the feamen, I hoisted my flag; and, having ordered The Ruby, " with two fire-ships to attend me, I stood in with them, leaving "the great ship without, as drawing too much water. But "coming very near, they galled us fo extremely, and finding the "fire-ships could not get in, I judged it best to retreat without " fhot, and there anchored: and immediately called all the cap-"tains, where it was refolved to attempt them in the morning, "with all the third and fourth rates, and fire-ships. But, after "drawing them into four fathom and a half of water, I found "we could not do our business, the water being shoal; upon "which, I ordered three fire-ships to prepare themselves, to at-"tempt the burning them, going myself with all the barges "and tenders to take them up, if, by the enemies shot, they "fhould mifcarry. Indeed, I may fay, and I hope without "vanity, the fervice was warm; yet, God be praifed, fo effec-"tually performed, that, notwithstanding all their shot, both "from their ships and forts, two of our fire-ships had good suc-"cefs, by burning them; the other, by an unfortunate fhot, fet "on fire, being just going on board the enemy; indeed, so brave "was the attempt, that I think they can never be fufficiently "rewarded; and I doubt not, but their Majesties will do them " right.

"The third French ship being run a-shore, and observing the people on board to go on shore by boats-full, I ordered the St. "Albans and Reserve, and others, to sire upon her, judging it might cause them to quit her; and after having battered her H h h 2 "for

"for some time, I observed she made no resistance; I took all "the boats armed, and went aboard her; I found abundance of "men on board, and several wounded; but no officers; and "having caused all the people, as well those who were wound-"ed, as others, to be taken out, I fet her on fire; and, had I "not had timely notice by my fcouts, that thirty ships were "flanding with us, had fent all the French on shore, who are " now very troublesome to me. The ships we saw, proved to be "Sir John Ashby, and the Dutch coming from the westward: we " are proceeding together to the eastward to La Hogue, where I "am informed, three or four of the enemy's ships are; and; "if fo, I hope God will give us good fuccefs: I expect to find "the admiral to-morrow, where, I hope to hear he has destroyed " fome of the enemy's ships, having left him in chase of them " last night, standing to the eastward, and pretty near them, as "I judged. My Lord, I hope you will excuse me, if I presume " to pray you will use your interest with the queen, that a re-" ward may be given to the three captains of the fire-ships, and "feveral of the others, for greater zeal, and greater bravery, I "never faw: I pray your excuse for being thus tedious and par-"ticular. Pray God preferve their Majesties, and that their arms " may be ever crowned with fuccess by sea and land, shall be the " prayers and endeavours of, &c.

P. S. "Captain Heath burnt Tourville's ship, The Royal Sun, which "was the most difficult; Captain Greenway burnt the other, called "The Conquerant; The Admirable was burnt by our boats; Captain "Fowlis attempted The Royal Sun, but was fet on fire by the "enemy's shot to the deferves as well as the others". (i)

<sup>(</sup>i) Confide Lines of the Amirals, &c. vol. 4. p. 287.

The most descring persons are generally the objects of envy. By its malignancy, the officers concerned in this gallant action were neither encouraged nor promoted. Sir Ralph himself, against the inclination of his sovereign, was afterwards stript of all his employments. But those shafts which struck him out of these, could not wither his laurels. His laurels, those honours gained in the service of his country, continued to adorn his brows, in their full bloom and vigour, shone superior to the acrimony of the times, attending him in his private as well as public life, and consecrating him to immortal same. Retired thus, and thus revered, he lived the remainder of his time, about nine years, upon his own estate, which was very considerable. He died in January 1707, and was interred in Westminsterabley, with a solemnity suitable to his merit.

George Delaval, of Delaval, Esq; had a genius not only for arms, but the cabinet. He was appointed by her Majesty Queen Anne, envoy extraordinary to the King of Portugal, in the room of the Earl of Galway, whilst he was only a captain of a man of war, on the 11th of Oct. 1710, and on the 14th of December following, he was sent ambassador plenipotentiary to the Emperor of Morocco, with instructions to treat for horses and provisions, for the confederate army in Spain. He was raised for his services to the high rank of admiral. He was killed by a fall from an unruly horse, as he was riding out to divert himself after dinner, near his house, June 22d 1723.

Sir Chaloner Ogle, Knt. was born at Kirkley by the river Pont, and was a younger brother of the late Dr. Ogle, a physician at Newcastle upon Tyne. Being destined to try his fortune in his majesty's navy, he was very early advanced by his personal merit and

and courage to the command of the Swallow Man of War, wherein he took Roberts, the famous pirate, on the coast of Africa, Feb. 5th 1722; whose story, and Captain Ogle's taking him, is thus described by the ingenious Mr. Campbell in his naval history of King George I. whose relation I prefer to the brave captain's in his letter to the Lords of the Admiralty, his pen not having the politure of his sword.

"There was among the pirates, on the coast of Africa, one "Roberts, a man whose parts deserved better employment; he "was an able seaman, and a good commander, and had with "him two very stout ships, one commanded by himself, of 40 "guns, and one hundred and sifty-two men; the other of 30 guns, and one hundred and thirty-two men; and to complete his squadron, he soon added a third, of 24 guns, and 90 men.

"Captain Ogle was in The Swallow, and was cruifing off Cape "Lopez, when he had intelligence of Roberts's being not far from "him, of whom he went immediately in fearch, and foon after discovered them in a very commodious bay, where the biggest and the least ship were upon the heel, scrubbing. Captain "Ogle taking in his lower tire of guns, and lying at a distance, Roberts took him for a merchant-man, and immediately ordered his confort, Skyrm, to slip his cable, and run out after him. Captain Ogle crowded all the fail he could to decoy the pirate, to such a distance, that his conforts might not hear the guns, and then suddenly tacked, run out his lower tire, and gave the "pirate a broadside, by which their Captain, Skyrm, was killed; "which so discouraged his crew, that after a brisk engagement, "which lasted about an hour and a half, they surrendered." Captain

"Captain Ogle returned then to the bay, hoisting the king's co"lours, under the pirate's black flag with a death's head in it.
"This prudent stratagem, had the defired effect; for the pirates,
feeing the black flag uppermost, concluded the king's ship had
been taken, and came out full of joy to congratulate their
confort on the victory. This joy of theirs was, however, of
no long continuance, for Captain Ogle gave them a very warm
reception; and though Roberts fought with the utmost bravery,
for near two hours, yet being then killed, the courage of his
men immediately funk, and both ships yielded". (k)

For this fervice, Captain Ogle was knighted in May following, 1723, and afterwards rose to the highest stations in the navy; being appointed rear-admiral of the blue in July, 1739; rearadmiral of the red in March; 1742; vice-admiral of the blue in August, 1743; admiral of the blue in June, 1744; admiral of the white in July, 1747; and admiral and commander in chief of his Majesty's fleet, on the death of Sir John Norris. As he was a brave commander himself, and owed his own advancement chiefly to his merit, fo he was usually forward to distinguish it in others, and promote it. To him we are indebted for difcerning it in a nephew of the late Colonel Bladen, commissioner of trade, and late owner of the cftate of Barmore in this county, and raifing him to the command of the Flamborough Man of War at Jamaica, his commission bearing date March 20th 1733. This was the present great admiral, Sir Edward Hawke, Knight of the Bath, whose courage and conduct has contributed so much to the glory of the British arms by sea, that his Majesty has settled 2000 l. per annum. on him for his own life, and the lives of his two fons.

<sup>(</sup>k) Campb. vol. 4. p. 471, 472, 473.

Sir Chaloner died in April, 1750; and in July, 1751, Lady Ogle, his widow, married Lord Kingston, an Irish peer.

Such are the great Captains which do honour to Northumberland! May we never want fuch to command our fleets and armies, and to chastife the enemies of Britain!

Secondly, of great scholars. In this number must be included those two eminent physicians, William Turner, and Thomas Gibson, cotemporaries, and both born at Morpeth.

William Turner, A. M. and M. D. received his first academical education at Christ's College, in Cambridge. His tutor was the learned George Folbery, S. T. P. preceptor to the Duke of Richmond, brother to King Edward VI. He was elected fellow of Pembrokehall, of which his tutor was then master, who died in 1540. His countryman, Bishop Ridley, was then fellow of the same college; between whom there was a great intimacy and friendship; both ftrenuous advocates for the dawning reformation. On the happy accession of King Edward VI. to the throne, Dr. Turner retired from his college to the court, accepting of the offer of being domestic physician to the Protector, the Duke of Somerset; with whom he was in fuch esteem, that he was promoted to the deanery of Wells, being a divine as well as a physician. In the beginning of the next reign, he exposed himself to the resentment of Bishop Gardiner, by writing a book, intitled, The hunting of the Romish fox. The bishop cast him into prison. By fome means or other he got out, and escaped the vengeance of that bloody prelate, by crofling the feas. He took refuge in Germany, where he lived genteely by practifing physic. On the death of Queen Mary, he returned with joy to his mother-country, and was refettled in his deanery.

He was author of two books of Natural History, one of birds, and the other of botany. The first is a comment upon Pliny and Aristotle, upon birds, with a particular and curious account of the birds observed by him in Northumberland. It is thus characterized by Dr. Merret, in his Pinax—Mole parvum, sed judicio majorem. It is a very scarce book. It is in Latin, in a neat stile; published 33 King Henry VIII. 1544, and inscribed to Edward Prince of Wales.

His book of botany was printed, 5 King Edward VI. 155!, under the title of—An English herbal, with cuts, folio. It is faid to be the first of that title published in England. Such plants as he observed in his exile, in Germany, are included in it, as well as those of his own country; and those that are scarce or curious in his native county of Northumberland, he does not forget to mention, and their place of growth. It is in the stile of that age, and in the old black letter; some of the cuts expressive enough of the plants, though done upon wood. It is not so scarce as his book of birds.

In Gesuer, there is also an account of the river and sea-fishes observed by him in Northumberland, presented to that learned author, his correspondent. It is much valued, being generally cited by the most learned Icthioligists of later times.

He died, 7th July, 1598; and was interred under a monument, in St. Olave's church, in Hart-street, London (1).

Thomas Gibson is not behind his countryman, Dr. Turner, in medical and literary fame. Bale bestows on him great encomiums,

<sup>(1)</sup> Carter's Hift. of Cambridge.

declaring, that he performed Ægritudinûm fanationes incredibiles, incredible cures of difeases; and that it would be a great felicity to mankind to have so valuable a life prolonged, which he sincerely wished (m). His private studies were directed much the same way with his brother Turner's, forwarding with zeal both the reformation and the medical art, writing many theological tracts, and a botanical piece, on the nature of herbs. The precise time of his death is not known. He was alive in the last year of Queen Mary.

Next to these two celebrated physicians and reformers, I must name those two learned prelates, Nicholas Ridley, D. D. Bishop of London, and George Carleton, D. D. Bishop of Chichester; also the eloquent, loyal, and pious Richard Holdsworth, D. D. master of Emanuel College, in Cambridge, &c. Valentine Cary, D. D. bishop of Exeter; and that great orientalist, Robert Calvering, L. L. D.: bishop of Peterborough:

Nicholas Ridley, D. D. bishop of London, in whom the pious King Edward VI. so much delighted, was born in Haltwefel-parish, and was brother to John Ridley, of Wall-Town, and to Hugh Ridley, of Unthank, Esqrs. and cousin to Nicholas Ridley, of Willimoteswick—castle, Esq; mentioned by Camden (n). The free grammar-school of Newcastle upon Tyne had the honour of giving him his sirst education, and Pembroke-hall in Cambridge of compleating it; the latter famous for religion and learning, being stiled in the Royal. Grants—"The noble, and renowned, and most precious college, "wonderfully shining among all places in the university;"—and

<sup>(</sup>m) Bal. Scriptor. Britan. Centur. ix. 1559.

<sup>(</sup>n) Camden's Britannia.

by Queen Elizabeth, on passing by the college-door, honoured with that venerable and endearing expression, worthy of a princess,— "O antient and religious house!" Usually called, Collegium Episcopale, from the number of learned and eminent prelates educated in it. In this college he was first admitted scholar; and, after taking his degree as batchelor of arts, was elected fellow in 1524. His literary fame and merit was fo great, as to procure him the love and careffes of both universities. Cambridge strove to keep him, Oxford to transplant him, by making him an offer of a vacant fellowship in University-college, which he declined. In 1525, he took his mafter's degree, and made a fhort tour to France, vifiting the learned in the university of Paris. He was chosen proctor at Cambridge in 1534; and, taking his degree of batchelor of divinity, he was made their chaplain, and one of their public readers. Honours and preferments came now thick upon him. Archbishop Cranmer presented him to the vicarage of Herne in East-Kent, gave him a prebend in his church of Canterbury, and got him made chaplain to K. Henry VIII. Pembroke-hall chose him for their master, 1540, when he took his degree of Dr. of Divinity; and, about 1543, they prefented him to the living of Sobam in the diocese of Norwich. His patron, the archbishop, procured him a prebend in the church of Westminster. King Edward VI. in the first year of his reign, 1547, preferred him to the See of Rochester. In 1550, he translated him to the See of London. A little before his death, he nominated him to the See of Durbam, to which the enfuing troubles prevented his being confecrated. His royal patron died July 6th, 1553; and he himself ascended from an episcopal, to a celestial throne, by a glorious martyrdom, Oct. 6th, 1555, in the 3d of Queen Mary, after the fum of ten thousand pounds had been offered for his life, by his kinfman, the Lord Dacres. He was of a low stature,

but of a great foul; endowed with all the graces and accomplishments that adorn the priesthood, such as recommended himto be one of the compilers of our most excellent liturgy. Godhad bleft him with a graceful elocution, an excellent judgment, a happy memory, and a wonderful courage, which he employed zealously in his fervice. In his private college, the facred writings were fo much his study, that lie had a great part of them by heart. In his pulpit, with a becoming zeal, and just indignation, he rebuked vice in all its forms, and opposed it with the magnanimity of a truly christian bishop, neither overawed by the found of titles, nor the pomp of great names, preferring the conscientious discharge of his duty before either the smiles or frowns of men. Ill customs he would break through with a resolution rarely to be met with, disdaining to accept his bishoprick of Rochester, but on terms that do him honour. His clergy he regarded, in reality, as his own family, and cherished the lowest with a tenderness becoming his order. When he found humble and modest merit under the pressures of the world, he himself would look upon it with the affection of a gardener on a neglected vine, and offer his hand for its weak and feeble tendrils to climb by, and flourish under the influence of his kinder fun. The most pressing follicitations from men in power, could not prevail with him to with-hold his patronage from fuffering virtue. He had a noble feeling for diffress. He would join in no measures with the court to the prejudice of learning and learned men. Our countrymen of Clare-Hall, of whom it was then full, had reason to love him, for abhorring and defeating a scheme, calculated by facrilegious men, for their ruin; who, not content with the deprædations they had already made in the church, with a shameless brow attempted to lay both religion and learning under the greatest discouragements, to aggrandize themselves.

His care for the poor was no less, than his care for lettered and oppressed virtue. The London-poor were more immediately under his eye, for whom he procured an ample support. The method he took to do it in, I shall give in the words of the ingenious author of his life, the Reverend Mr. Downes, though I might do it in his own, from his farewel-letter, preserved among many others of his, in a curious and valuable collection of letters of the martyrs, printed by Day, in 4to. 1564 (0).

"In the beginning of the year 1553, Bishop Ridley preached " before the king, who began to decay apace, at Westminster. The "fubject he chose to discourse upon, was charity; and he, in "very moving and affecting terms, pressed the king to take care, "that a constant and settled maintenance should be provided for "the poor. This discourse made so great an impression on the "young king, that he fent for the bishop; and after he had or commanded him to fit down, and be covered, returned him " his hearty thanks for his good exhortation; and defired him to "communicate to him his opinion, what would be the best expe-"dient, effectually to bring to pass so great and good a design." "the bishop was very much pleased to find the king's inclina-"tions fo forward; and with tears of joy, told him, that the "London-poor, by reason of their numbers, stood in need of his "more immediate concern; and that he would therefore advise "him, to order letters to be wrote to the Lord-Mayor and Alder-"men, to take this affair into confideration, and project a scheme "for the relief of the poor, who swarmed in great numbers

<sup>(0)</sup> In this letter he takes his leave of all his near relations, addresses them all by name, also Cambridge, the place of his education, the college he was of, and the several places to which he was preferred. It contains a most moving and affecting recognition of the most material rassages of his own life.

"about."

"about the city. The king approved of this advice, and ordered letters to this effect, to be forthwith dispatched, before he would permit the bishop to go out of his presence.

"Bishop Ridley, furnished with these letters and instructions, " delivered them to Sir Richard Dobbs, then lord-mayor of London; "who immediately called together as many of the aldermen and common-council, as were thought fit to be advised with "in the prefent business; and not only with great earnestness " pleaded the cause of the poor, and pressed them to a forward " zeal in this affair; but introduced Bishop Ridley into the council-"chamber of the city, to be their advocate, and to guide and " affift himself and his brethren in their councils. After divers " confultations, they refolved, that a general contribution should "be made by all the wealthy citizens, to the advancement of a "work, fo highly conducive to the public good. To this end "they were fummoned to their respective parish-churches, and "there by the lord-mayor, the feveral aldermen, and other grave "citizens, exhorted to contribute generously and bountifully " to this noble defign; and they were urged to it the more ear-" neftly, by fetting before them the many great advantages that "the city would reap, if the poor were removed out of their "freets, lanes, and alleys, and bestowed and provided for in "proper hospitals. It was therefore moved, that every man " should fignify, what he would give towards the building and "finishing such hospitals; and how much they would contri-"bute weekly toward their maintenance, until they were fup-" plied by more liberal endowments. The motion was readily "accepted; every man fubfcribed according to his ability, and "books were kept in every ward of the city, in which the fums, " each person subscribed, were set down; which books, when " the

"the contributions were finished, being delivered to the mayor, "were by him put into the hands of the king's commissioners.

"In the scheme drawn up for the relief of the poor, they "were ranged under three divisions: in the first were placed the " poor distressed orphans; in the second, the sick, the lame, and "infected; in the third, the lazy and licentious vagabonds. For "the orphans, Christ's Hospital was provided, where they were. "furnished with necessaries, brought up in a virtuous and reli-"gious manner, and fitted for some honest business. The hospi-"tals of St. Thomas in Southwark, and St. Bartholomew in West-"Smithfield, were appointed for the reception of the wounded, "fick, impotent, and maimed: and the king gave his palace of " Bridewell, erected by Henry VIII. for the reception of vagabonds, "flurdy beggars, and flrumpets; where they were to receive due "correction, and be kept to hard labour. For the better endow-"ment of this, and the other hospitals, and to furnish them "with a competent maintenance, the king dissolved the hospital "in the Savoy, for the support of pilgrims and travellers; but " which was now employed to most scandalous uses, and made "a shelter for lewd and lazy persons, and the harbour of thieves "and vagabonds: and he gave their lands, amounting to fix "hundred pounds per annum, and all their furniture, to the city "of London, for the maintenance of these new foundations." (p)

Such was the piety and charity of this great prelate. He was justly the admiration of the age he lived in, and will ever resect a lustre upon this his native land, and be considered as one, who had a godlike dignity and elevation of foul, superior to all the

<sup>(</sup>p) Lives of the Compilers of the Liturgy of the Church of England, by the Reverend. Mr. Downes.

transitory grandeur of this world. There is an excellent print of him in Mezzotinto by the ingenious Mr. Houston, in Mr. Rolt's history of the principal reformers.

George Carleton, D.D. Bishop of Chichester, was born at Norhamcastle by Tweed-side, of which his father was captain; and sent his fon to Houghton le Spring, near Durham, to be educated with other young gentlemen under the eye and care of the famous Bernard Gilpin; who, like the fun, cherished with his light all ranks and degrees of men, as well within his parish, as out of it; and, like that great luminary also, did not shine only within the fmall limits of a country-parish, but let it spread, many times at the peril of his own life, through lands covered with darkness and error, letting the world see the beauty and loveliness of a good life by the heavenly splendor of his own. Infpired by the divinity, as it were, of his example, Bishop Carleton, had all the graces that are charming in a divine, was the admiration, not only of his own college of: Merton, in Oxford, but also of that university, and of the synod of Dort, to which he was fent, with three other eminent clergymen, by King James I. He wrote the life of his dear friend, Mr. Gilpin, in elegant Latin (q), and some other pieces (r). He died, I K. Charles I.

Richard Holdsworth, S. T. P. was born at Newcastle upon Tyne. He was named after his father, a clergyman, who, after a good school-education, sent him to St. John's college, in Cambridge. He

<sup>(</sup>r) One, intitled, A thankful Remembrance of God's Mercy: another, intitled, A Confutation of Judicial Astrology.

was incorporated at Oxford, 15th July, 1617. He was eminent for his learning in both universities. He was made chaplain to Sir Henry Hobart, Lord Chief Justice of the Common Pleas. His Lordship presented him to a living in the west-riding of Yorkshire, which he exchanged for the rectory of St. Peter le Poor, in London, in 1623, or 1624 (s). Here he exerted every faculty of his foul for the good of his people, even at the peril of his own life, not deferting them in the dangerous fickness in 1625, attending them with his prayers, his counsel, his charity, and like a faithful fleward and physician, administring to all their necessities, withholding no consolation from them in his power. He filled and adorned some of the highest stations; was chosen, without any folicitation, divinity-professor at Gresham-college in 1630 (t); made archdeacon of Huntingdon, 12th January, 1633, on the death of Dr. Owen Gwyn (u); and was at St. Peter le Poor, when the general return was made for churchwardens, in 1636 (v). He was elected master of Emanuel college, in Cambridge, in 1637; also Margaret-professor of that university by an universal suffrage; their vice-chancellor for three years together, 1640, 1641, 1642 (w). About the latter end of the year 1643, he had a grant of the deanery of Worcester, after declining the acceptance of the bishoprick of Bristol. In 1644, he was turned out of all his preferments by the parliament (x), and committed prisoner to Ely-

house (y), for his loyalty and steady principles. His irreproachable life appearing in evidence for him, he regained his liberty. The discharge of his duty being nearer his heart, than the fears of death, and being as little afraid of the frowns of men, as ofthe approach and peril of a stern disease, or the dishonours of poverty, he vindicated the doctrines of the church of England; with an eloquence and force that exposed him again to the refentment of his adversaries, who ordered him into custody, and thut him up for three or four years in the tower (z); with this remarkable, but honourable declaration in his favour,-" That "if he was permitted to preach, he would undo all that they "had done." (a) To the cruelty of imprisonment and sequestration, they added that of plunder. He was very dear to the king, who defired to have him with him under his confinement both at Holmby-house, and the Isle of Wight, but was denied that. favour by his enemies, being only permitted to fee him at Hampton-court. His majesty's death afflicted him more than all the other severities of his fortune, whom he survived but a few months, dying in August, in the fame year, at the age of fiftyeight. He was interred in his own church of St. Peter le Poor; on the fouth-east side, where a mural monument was erected to his memory, with the following infcription, drawn by his friend, Bishop Brownrigg, of Exeter (b).

Valen-

Valentine Cary, D. D. Bishop of Exeter, was born at Berwick upon Tweed, and descended from the Carys, Barons of Hunsdon. He was twice fellow of St. John's college, and intermediately of Christ's college, in Cambridge, of which he was warden. He was vice-chancellor of that university in 1612; rector of Epping, in Essex, and afterwards of Tost, in Cambridgeshire; Dean of St. Pauls; and for his genteel and polite breeding, and excellent learning, was, at length, preferred to the See of Exeter. To the poor of that city, when visited with the great sickness, he extended his charity with a liberal hand. He died in 1626; and was interred under a plain stone in the cathedral of St. Pauls. A sepulchral memorial was also erected for him in his cathedral of Exeter (c).

Robert Calvering, L. L. D. Bishop of Peterborough, noted for his skill in the oriental languages, was born in Newcastle upon Tyne, and descended from the Claverings of Till-mouth, a branch of the house of Calleley (d). He was made the King's Hebrew professor at Oxford, 12th May, 1715; to which a canonry of Christ's church in that university is annexed. He was preferred to the bishop-rick of Landass, and the deanery of Hereford, 31st August, 1724; and translated to the bishoprick of Peterborough on the death of Dr. White Kennet, in January 1728-9; holding his professorship, and his living of Marsh, in Buckinghamshire, in commendam. He died in July, 1747.

Thirdly, of great Patrons of Learning. The most eminent patron of learning is Robert Woodlark, D. D. He was born in Northum-

<sup>(</sup>c) Stow's Survey of London, p. 776.

berland, but at what place is not precifely known. By licence from K. Edward IV. 1459, he founded St. Catherine's-hall, in Cambridge, for a master, and three fellows. He was then provost of King's college, to which he was appointed, 17th May, 1452. He was chancellor of that university in 1459, and 1462. The living of Kingston being vacant; he was presented to it by the college-trustees, Thomas Rotherham and Walter Field. He resigned it, 11th May, 1458; and, 3d April, 1460, he also resigned the free-chapel of Wittleford-bridge. He was preserved to the rectory of Coton, 1471; and of Fulburne St. Vigarius, 1473.

Fourthly, of great Patrons of Trades. The first deserving our notice, is Roger Thornton, the Elder, of Newcastle upon Tyne; and next, a gentleman now living, Sir John Hussey Delaval, Baronet.

Roger Thornton, Esq; was born at Witton-castle, by the river Font, as attested by a celebrated antiquary (e). He was bred a merchant at Newcastle, and is the most eminent patron on record, for a private man, of that corporation; to whom they stand obliged for the Town-Court, since rebuilt, and many other instances of public spirit and generosity. His estate, great for those times, 800 marks per annum (f), was frugally and wisely managed, to encourage public and private industry, and to felicitate society by acts of beneficence and charity. He died, 3d January, 1429; and was interred in All-Saints church, in Newcastle, by the altar, on the south side, opposite to the vestry.

Sir John Hussey Delaval, Baronet, is the greatest instance of public spirit in the encouragement of commerce, that this part of the world hath produced; who at his own private expence made

word freihigh Berghern Dung

<sup>(</sup>e) Lel. Itin. vol. 6. p. 56.

a commodious harbour at *Hartley*, by cutting a canal through a folid rock, 900 feet long, 54 feet deep, and 30 feet broad; employing about 500 men till it was finished. On *Tuesday*, 20th *March*, 1764, two ships sailed in, with full sails, for the first time; and on *Thursday*, 22 *March*, the *Warkworth*, a vessel carrying 13 keels of coals, sailed out; being the first that did so after it was opened.

Fifthly, of the patrons of rural and domestic arts. It is with pleasure I can mention, without offence to other gentlemen, Robert Fenwick, of Lemington, near Alnwick, Esq; who, for his laudable ambition of Planting, hath received a just mark of distinction from an honourable society, the society for the encouragement of arts; being presented with a Gold Medal, 1764, for having planted 4100 Scotch firs.
